REMARKS ON THE PAIN CAUSED BY GALL-STONES.

By Arthur Leared, M.D., M.R.I.A.,
Senior-Physician to the Great Northern Hospital.

Every one who has made many examinations of the dead body is aware that calculi are often found in the gall-bladder, in cases where no symptoms had indicated their existence. From these facts we may infer the frequency with which gall-stones occur.

In another large number of cases certain symptoms are, during life, with the highest degree of probability, attributed to the presence of these bodies. There are, however, other symptoms less generally, or not at all recognised as such, which also belong to gall-stones. To these I purpose especially to draw attention.

The absolute proof that any symptoms are caused by gall-stones, is only afforded from their appearance when discharged from the body. This discharge is almost invariably effected along with that of the fæces, and the presence of calculi are from this cause almost as constantly overlooked. Reliance is, however, commonly placed upon certain vital symptoms, and two of these, namely, jaundice and severe pain, are, when associated, generally regarded as pathognomonic.

There are four positions in which a gall-stone may be placed so as to give rise to active symptoms, namely, in the common duct, in the cystic duct, in the hepatic duct, and in the ducts within the liver itself, as I shall now attempt to show. The accompanying symptoms to some extent indicate the seat of obstruction in each case respectively. The passage of a calculus through the common duct usually occasions severe pain and vomiting, and if the passage be protracted it inevitably causes jaundice.

The passage of a calculus through the cystic duct may cause pain and vomiting, but probably never causes jaundice, because the flow of bile from the liver into the intestine is not interfered with. Jaundice in such a case can only happen from the absorption of bile retained in the gall-bladder, but there is no proof that jaundice has ever occured from this cause.

The passage of a calculus through the hepatic duct may also produce pain and vomiting, and if the obstruction of the duct be complete and somewhat prolonged, will also certainly cause jaundice.

Obstruction of a duct or ducts within the liver may or may not produce jaundice, and is stated to induce a condition closely resembling intermittent fever.*

Rigors may happen in any case of gall-stone contained within a duct, but it seems to be only when this occurs within the liver itself that the intermittent type is assumed.

It will be seen from the foregoing, that the passage of gall-stones is not necessarily accompanied by jaundice, for in certain cases the mechanical arrangement precludes its development, whilst in the remaining cases no jaundice will ensue if the calculi pass through the ducts with sufficient quickness. On the other hand experience shows that the passage of these concretions is not always attended by pain.

Some persons feel pains of every kind much more acutely than others; the temperament of the individual has something to do with this; probably the difference is very obvious when parts of the body not naturally sensitive are affected. The stomach when healthy is almost devoid of common sensibility; but gastric pain is a symptom of dyspepsia in some persons, while other dyspeptics never suffer any pain in the stomach.

Applying this to the bile passages we come to understand why it is that the passage of calculi through them is, in the case of some people, attended by great agony, while, as proved by many recorded observations, others discharge them without suffering. The relative amount of mechanical difficulty with which the stone is passed in different cases, without doubt influences the degree of pain experienced in each instance. In one case the ducts will dilate with more ease than in another, and this probably depends upon the state of relaxation, or of tonicity which pervades all the tissues of the body. This, however, cannot account for the absence of pain in a case in which, judging from the size of the calculus, the ducts must have been greatly stretched and irritated by its passage.

---

* "A Treatise on Gall-stones. By J. Thudichum. 1863. Page 180.

It is a curious circumstance that a spot a little below the xiphoid cartilage is almost invariably the seat of gastric pain, although from the size and relations of the stomach to other parts, its seat might be expected to vary greatly. The pain caused by gall-stones is, according to my experience, less often referred to its proper seat, namely, about two inches to the right of the epigastrium, than to other regions. More frequently the pain is referred to the epigastrium itself, and this circumstance makes it often most difficult to distinguish between gastric pain, and the pain arising from gall-stones. Gall-stone pain is also experienced in the region of the navel, and probably also in every part of the abdomen. Trousseau, indeed, lays it down as an axiom that the possibility of gall-stones being the cause should be taken into account in every case of persistent abdominal pain. I entirely concur in this, and would add, that in such cases, especially if the lower portions of the abdomen be the seat of pain, the possibility of its being caused by the passage of a calculus from the kidney should also be kept in view. I have met with the case of a gentleman who was subject to severe attacks of abdominal pain, which was looked upon and treated for years as simple colic, and until the escape of a small calculus from the urinary bladder was found to be associated with one of the paroxysms.

Dr. Copland says :—"Patients with biliary calculi often complain of a sense of weight and oppression at the epigastrium and right hypochondrium, with cardialgia and various dyspeptic symptoms, especially after a meal." My experience coincides with this, except in the particular that the pain is generally referred to the epigastrium alone. As a general rule, however, gall-stones are seldom thought of except in connexion with the acute suffering which they cause in passing through the ducts. But it will be observed that Dr. Copland speaks of cardialgia caused by the presence of calculi in the gall-bladder. This pain is different in character from that which arises from their presence in the ducts. It is altogether less spasmodic and less acute, and along with it there is generally more or less tenderness, not only in the epigastrium, but also over the gall-bladder. I was formerly disposed to regard cases of this kind as arising from conjoint affections of the stomach and the duodenum. More extended observation has led me to the conclusion that the symptoms are far more frequently due to the irritation of the gall-bladder by calculi, and occasionally to its distension with bile.

The duodenum and gall-bladder are placed so close to each other as generally to render it impossible to discriminate, simply by presence of pain or tenderness, between the affections of the two organs. Now the duodenum enjoys a remarkable exemption from disease, while the gall-bladder, as we have seen, is very prone to contain gall-stones, which not only irritate, but not unfrequently inflame its mucous surface.

The circumstance, that in a certain number of instances of mere gastric pain more or less jaundice ultimately supervened, has also helped me to the conclusion that the gall-bladder is often in such cases the true seat of disease. Let us now consider the fact of the pain being transmitted to the epigastrium instead of being felt where it is produced.

A calculus in the urinary bladder, or even in the kidney, is commonly attended by pain in the penis, or down the thigh. Irritation in the midst of the intestines is felt at the anus, or in the nose. In the same way the irritation caused by a calculus in the gall-bladder is felt as pain in the epigastrium, with or without accompanying pain in the gall-bladder itself. The epigastrium, in a word, seems to be the chosen seat of pain which does not properly belong to it. Affections of the stomach, of the gall-bladder, and most probably of other viscera here make themselves known. I have, indeed, elsewhere shown that in organic disease of the heart, pain in the epigastrium is in certain cases the only symptom of which the patient complains.* It is true, however, that in these cases the pain seems to be due to a secondary affection of the stomach.

Ordinary gastralgia, by which I mean pain with tenderness epigastric region coming on some time after a meal, usually yields readily to appropriate treatment. In some instances the pain is of the true neuralgic kind, and must be treated as such.† In other cases the pain is also induced by taking food, but does not yield to treatment. Nothing can be better marked than are these three varieties of pain having the same locality, by the difference in the effect of remedies. To these three classes of cases must be added a fourth, which cannot be grouped with the others, because, as in all that relates to it, it is subservient to no rule. At one time, or in one case, it yields to treatment, while at another time, or in another case, treatment has no effect. I refer to hysteria, which is in females another fruitful cause of epigastric pain.

Now, the cases of epigastric pain which do *not* yield to treatment, and which there is no reason to suppose depend upon hysteria, will be almost surely found to be caused by the irritation of calculi, or of bile retained in the gall-bladder. Such calculi are not unfrequently the size of a walnut, and when solitary sometimes reach much larger dimensions, or else a great number of small ones exist together. In any case it is not to be wondered at if much irritation should be induced by their presence in the gall-bladder.

I have notes of some cases in which simple epigastric pain of no violence, and induced by taking food, like ordinary gastralgia, has proved to be due to gall-stones. The proof lay in the fact that an attack of acute pain, evidently caused by gall-stones, with or without jaundice, ultimately supervened. But besides such positive proofs as these, and the negative evidence already mentioned, there is another matter which plainly points in the same direction —namely, it commonly happens that although the pain is strictly epigastric, it will be found on careful examination that while tenderness on pressure, in cases in which it arises from the stomach, has the same seat, the tenderness in the gall-bladder cases is felt in the region of this viscus.

The following case illustrates the great difficulty of determining whether even pain of the most severe kind originates in the stomach or is transmitted to the epigastrium. The wife of a clergyman came to town and put herself under my care on account of severe attacks of gastric pain. She looked almost completely worn out by her sufferings. The first seizure happened twelve years previously, after the shock caused by learning at the same time of the death of two friends. She had been ever since subject to similar attacks, which lasted four or five hours, and were induced by any indiscretion of diet, or by mental emotion. The pain began at the epigastrium, and extended over a great part of the abdomen. After this had continued some time vomiting came on. Great prostration, which did not quickly subside, ensued after each attack. The patient had been slightly jaundiced on one occasion. There was well-marked tenderness on pressure over three of the mid-dorsal vertebræ. She had been seen by several medical men of eminence, and various opinions had been held. By one the symptoms were attributed to spinal disease; by another to stricture of the pylorus; gall-stones had been suggested by a third. My own view was, that the case was either one of gall-stones or of neuralgia of the stomach, and it seemed desirable to test the matter by trying the effect of treatment for neuralgia. The trial was accordingly made, but with no good result, and the patient returned to the country unrelieved. She soon after fell into a state of great debility, and lay constantly on her back for six months, but during this time she was free from the painful seizures. At length, fourteen months after I had seen her, it was discovered that she had passed a gall-stone, which was sent to me by Mr. Harrison, of Braintree, her medical attendant. It is about the size of a filbert kernel, and weighs twenty-six grains. It is somewhat compressed at the sides, as if by the pressure of other calculi. This lady consulted me some months afterwards, but she had entirely got rid of her old troubles. She was able to walk about as other people do, and had regained flesh and strength.

---

* "Medical Times and Gazette."

† See my Paper.

How are we to explain the train of symptoms in this case? It is remarkable that the patient did not recover strength during the six months of freedom from her attacks above-mentioned, but was, on the contrary, confined to bed. After the expulsion of the gall-stone, however, she recovered rapidly.

There are two ways of accounting for the protracted illness of the patient, as well as her great sufferings. It is almost certain that at one time several gall-stones existed together in the gall-bladder. If we suppose that a single calculus was expelled after each attack, it is impossible to conceive either that the original supply could have been sufficient, or that they could have been produced fast enough to have caused the very numerous acts of expulsion and their accompanying symptoms, extending over a period of twelve years. It is possible indeed that the attacks might have been caused by one or more calculi, which did not usually pass into the intestine at all, but, after having for a time remained in one of the ducts, would slip back into the gall-bladder, to be the cause of renewed suffering. But taking into account the great number of the attacks and their intimate connection with exciting causes—considering also the persistent evidence of reflex irritation to which the spinal affection was evidently due, as well as the great muscular debility—it is almost certain that calculi while in the gall-bladder were, by their irritation, the persistent cause of constitutional disturbance, and that in this position they were also mainly the ever ready agents in causing the painful stomach attacks whenever excited, as already said, by conjoined irritation in that organ, or in the brain itself. Such a view does not, of course, exclude the probability that the pain was at times also caused by the *passage* of gall-stones.

I have at present a case under treatment, in which the patient, who is quite out of health, complains of what he calls a "languid pain" in the stomach when it is empty, which is relieved by taking food; but the pain returns much more strongly in about an hour afterwards, evidently induced by the act of digestion. He is also subject to attacks of biliary colic at long intervals. There is persistent tenderness over the gall-bladder, and the rectus muscle in this region seems to be constantly contracted. Medicines have been of little avail, except as palliatives. I have no doubt that his illness depends on the irritation of gall-stones in the gall-bladder.

Besides irritation of the gall-bladder from the presence of calculi, and of pain in the ducts from their passage through them, thickened bile without doubt produces like effects. *Post-mortem* examinations prove that the stored-up bile is sometimes as thick and as little capable of flowing as so much tar. In this condition it is probable that it irritates the gall-bladder, not merely mechanically, but by an acrid quality produced by its retention. According to Dr. Thudichum, bile undergoes a kind of fermentation in the gall-bladder, by which it becomes decomposed. The following case seems to have been one of the kind;—

A gentleman, accustomed to work hard at his profession as an artist, sent for me in March last on account of a very severe attack of gastric pain, with constant vomiting, which came on during the previous night. He had had a similar attack some months previously, and had been long much distressed by flatulence. He was not jaundiced, but a few days afterwards I found a well-defined tumour, about the size of a hen's egg, in the region of, and evidently formed by, the gall-bladder. It was not at all tender on pressure. Under the use of nitro-hydrochloric acid, and compound calomel pill nightly, this tumour soon vanished. The size, the shape, and the feel of the tumour indicated that it consisted of fluid. If the cystic duct had been obstructed by a calculus, this fluid might have been mucus, or a watery secretion from the gall-bladder itself. If, on the other hand, the common duct was blocked up from the same cause, it would most probably have consisted of bile. It was not for some days after pain had entirely ceased that the tumour disappeared, nor was the pain renewed, as if a calculus which had progressed for some distance through a duct, and then stopped, had again resumed its course. It seems, then, from these facts, that the case was one of over-distension of the gall-bladder, either from obstruction of the ducts caused by spasm, which we have no proof ever occurs, or from the unusual thickness and viscidity of the stored-up bile interfering with its outward flow.

The apparent effect of treatment favours the last view. If the remedies employed really stimulated the secretion of the liver, the dilution with fresh bile of that retained in the gall-bladder would tend to alter its quality, and thus make it capable of flowing through the ducts. I still trust to clinical facts, and believe that the human liver is capable of being excited to action by mercury, and probably by other drugs. Facts based on experiments upon the lower animals are not conclusive against this theory. What I have endeavoured to impress upon my readers comes to this—that in a considerable proportion of the cases in which epigastric pain is a prominent symptom, the gall-bladder, and not the stomach, is the seat of irritation.

I shall now offer a few details about the only fatality from gall-stones which I have met in practice.

A man, previously healthy, 22 years of age, was seized with severe pain in the right hypochondrium. Mr. Conolly, late of Aldersgate street, with whom I afterwards saw the patient, was called to him, and under appropriate treatment the patient seemed to have speedily almost recovered. On the fifth day from the seizure, however, he was slightly jaundiced, and the fæces were almost white in colour. He now complained of a throbbing sensation in the right side of the abdomen. From this time until the twelfth day of his illness, he daily grew worse; the pain became continuous and diffused; he was greatly exhausted; sweated profusely, and, towards the latter part of the time, had a constant desire to pass water, with painful micturition. On the following morning he declared himself much better; he had hardly any pain, and could micturate without inconvenience. The right side of the abdomen was now found to be remarkably dull upon percussion. In the afternoon of the same day a great change occurred. His pulse became rapid and thread-like, the skin cold and clammy, and he complained of agonizing pain throughout the abdomen. He died in about ten hours from the time this last change came on. Rupture of the gall-bladder was diagnosed.

On *post-mortem* examination, the right side of the abdominal cavity was found stuffed with coagulated blood, by which the viscera were to some extent displaced. The gall-bladder was found ruptured, and considerable part of it, together with a portion of the liver to which it had evidently been adherent, had disappeared by sloughing. The broken surface of the liver, together with portions of the gall-bladder, were black and ragged looking; the liver seemed to be healthy elsewhere. The gall-bladder had also been adherent to the stomach. In the common bile-duct, at an inch from its termination, a gall-stone, the size and shape of a large pea, was discovered. Up to the point at which the stone was impacted, the duct was dilated so as to admit a cylinder five-eighths of an inch in diameter.

This patient was unusually young to be the subject of gall-stones; but death happening in this particular way is, fortunately, a matter of extremely rare occurrence. It is also remarkable, that in this case the gall-stone was of so small a size.

◆

MEDULLARY CANCER.[1]

By Michael H. Stapleton, M.B. Dub., F.R.C.S.I.

Robert Grogan, aged 32 years, a labourer, married, and having a family, had been in perfect health until about eighteen months ago, when he noticed a small tumour in the gluteal region. It was not painful to the touch, and he sought no treatment until, alarmed by its increasing size, he applied to a doctor in the country whom, he said, punctured it, but that nothing came from it but blood. He was admitted into the Jervis street Hospital, under my care, on October 13th, 1868. The tumour then was about the size of half a cocoa-nut. It was strapped over with adhesive plaster, which, he said, had been applied to enable him to bear the journey, as he came from a long distance. On the removal of the adhesive plaster, there was seen at the summit of the tumour a dark circular spot, whose diameter was about the eighth of an inch, and around which was a discoloured and inflamed surface to the extent of about what might be covered by a half-crown piece. The rest of the integuments covering the tumour were normal in appearance. The tumour, although somewhat tense, gave a distinct sensation to the fingers of fluctuation.

In consultation with my colleagues it was agreed that this was a tumour to be let alone; but it was suggested it would be well to explore it. I accordingly punctured it at its base with a very fine exploring trocar and canula. When the trocar was withdrawn a single drop of grumous looking fluid escaped. A fine lacrymal probe was then passed through the canula, and was passed in its entire length without meeting the slightest opposition to its passage. Lint moistened with lead lotion, and covered with thin gutta-percha, was applied to the tumour, and the patient was directed to remain in bed.

On the following day the inflammatory symptoms were increased; the discoloured brown patch on the surface of the tumour was deepened in colour, and the whole tumour had taken a yellowish appearance; it was more tense, but it still gave the sensation to the touch of fluctuation.

In about a week after the brown patch sloughed, and was quickly followed by a dark coloured and bleeding fungus, the hæmorrhage from which was checked by the application of charpie moistened with spirits of turpentine. From this period the fungus daily increased until it reached the size you see represented by the cast on the table, and which was taken after death, which occurred on the 7th of November. I may say without the slightest degree of exaggeration the fungus represented by the cast is not half the size the fungus was during life, so much did it collapse after death.

There was a constant tendency in this fungus, at all times, to bleed, and once he lost a large quantity of blood by his leaving his bed and walking across to another bed which had been prepared for him. This fungus, after it had attained some size, very much resembled a brain from the number of convolutions upon its surface. Although this man's death was looked forward to, still it occurred in a sudden and unexpected manner. He raised himself up in bed, vomited about two pints of blood, fell back in his bed, and life was extinct.

Be it now remarked that all the time this man was in hospital, he never made any complaint as regarded his stomach. On the *post-mortem* examination, about four pounds of semi-coagulated blood was found in the stomach, which on being removed and the stomach having been washed out, an ulcer of the size of a shilling, with a bleeding point in its centre, was found, and from this point the hæmorrhage came which was the immediate cause of death.

The dissection of the tumour showed it to have been a soft medullary or encephaloid tumour; it much resembled brain, and was rich in a creamy juice. He did not seem to have any distinct capsule. Besides the tumour, there were several small bodies, some as large as small kidney-beans, and others still smaller, found in the gluteal muscle. The tumour lay upon the sciatic nerve, but did not enter the pelvis.

On examination by the microscope, the creamy fluid before mentioned was found to consist of cells of various sizes and forms; but free nuclei, suspended in a nebulous liquid, with a quantity of molecular matter, formed its greatest part. There was also a superabundance of oil-globules. I may also mention that the foot and the leg, to about half its extent (on the same side as the tumour), was elephantised.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Dr. Ogle's Cases of Abdominal Tumours.

(Continued.)

Case XXXV.—*Abscess below the ribs, displacing the kidney, in connection with encephaloïd carcinoma of the vertebræ.*

Mary A. W., æt. 39, admitted in January, 1863. Since November she had suffered from pain in the loins and left thigh, and from debility and loss of appetite. When admitted there was lateral curvature of the spine, and at the edge of and beneath the lower ribs on the left side a hard immovable tumour, two or three inches in diameter, was found; and lower down was also a soft and movable mass. The urine was free from albumen. She was treated with iodine of potash, and an opium plaster was applied to the affected parts. She went out of the hospital, but was subsequently re-admitted (March 11th), the tumour having increased, with a very cachectic appearance. Large quantities of blood became passed by the bowel, and she died March 25.

Post-mortem examination.—Thorax. Slight miliary scrofulous deposits were found in the left lung. The heart was natural.

Abdomen. There was encephaloïd carcinoma of the liver and ovary. The left kidney was found lifted up along with the pancreas by a collection of fetid matter, having the bodies of the vertebræ which were infiltrated by encephaloïd carcinomatous material, for its posterior boundary.* The kidneys contained "blocks" of fibrin in their substance. Cysts in the ovary were found to contain numerous hairs.

ADELAIDE HOSPITAL.

KIDNEY DISEASE SIMULATING ORGANIC DISEASE OF THE STOMACH.

(Under the care of Dr. Little.)

On Feb. 7th, 1868, a dock porter, aged fifty, was admitted. The patient said he had suffered from a bad stomach all his life, that is, he was easily sickened by rich food, and his bowels had been torpid; for the past two years he had been temperate, but previously had drunk heavily. For the past twelve months his stomach has become more and more, easily sickened, his bowels only acting every four or five days. He has lost flesh greatly. Two months ago suffered for a fortnight from pain in the right loin, shooting into the right iliac region, (but not into the testicle), and along the chest-wall towards the shoulder, it was so severe as to confine him to bed during its continuance, and since, he has vomited almost everything he swallowed. Till a fortnight ago the vomited matters consisted merely of food unchanged, they are now green.

---

[1] Read before the Surgical Society of Ireland on Friday, December 11th, 1868.

* A patient has recently died (September) under my care at the Hospital with abscess *behind* the right kidney, pushing forward this organ during life. The kidney was almost entirely replaced by a large mass of fatty growth, which also extended down the ureter to the bladder in a remarkable way.

When admitted vomiting was incessant, being provoked even by the smallest quantity of iced water ; his bowels had not acted for ten days. Iced milk and lime-water to be given in tea-spoonfuls, and a scruple of ox-gall dissolved in a pint of warm water as an enema.

February 8th.—Vomiting has been frequent since admission, the vomited matters being deeply tinged with bile, and containing a few specks of blood. Enema returned, merely coloured with fæcal matter. Tongue covered with thick cracked fur. Urgent thirst. Abdominal muscles somewhat rigid. Complains of feeling of lumps and fulness in epigastrium. Has been sleepless and somewhat delirious. Pulse 104, bounding ; heart's action violent ; at the ensiform cartilage, and over the space of a five-shilling piece, around it a loud rasping friction sound is audible. Has passed a pint of urine of pale sherry colour, sp. g. 1015, coagulable to one-third.

February 9th.—Vomiting continues ; delirium increased. Friction sound now audible over entire cardiac region. Iced milk and lime-water, and iced brandy and water to be given, and beef-tea enemata.

During the three succeeding days the vomiting was inconsiderable, the milk and lime-water being retained ; the friction sound continued ; the delirium increased, and with it there was constant twitching of the muscles. On the 13th he was comatose ; the urine gradually diminished in quantity ; he died on the evening of the 13th. Both kidneys were found small and shrivelled ; the heart was considerably hypertrophied ; there was abundant recent lymph on the pericardium ; the stomach and bowels were examined throughout, but were free from disease.

In this case the persistent irritation of the stomach, the hypertrophy of the ventricles, and lastly the recent pericarditis and the cerebral symptoms (uræmic poisoning), were plainly sequelæ of the renal disease.

HEART DISEASE IN WHICH THE SYMPTOMS DURING LIFE WERE REFERRED TO THE STOMACH.

(Under the care of Dr. W. G. Smith.)

On the 2nd of September, 1868, a young girl, aged nineteen, was admitted into the Adelaide Hospital, her prominent symptoms being distressing vomiting attended with severe gastric pain and tenderness.

She had always been a delicate girl, and two months since was attacked with pain in the chest and stomach, and constant retching and vomiting, which have continued up to the present. There was no evidence of her ever having had rheumatism in any form. The morning after admission she threw up two large cupfuls of yellow curdy matter, and it was observed that her conjunctivæ were yellow. Bile pigment was also found in the urine, but the skin remained of its natural colour. There was strongly marked pulsation in the cervical vessels, chiefly on the left side, and the cardiac action was much excited. The heart's impulse was strong and diffused, and on auscultation a loud systolic souffle was heard, traceable up the carotids, the rhythm being irregular, intermitting, and frequently tripled. Pulse 96, sharp and irritable. The feet and legs were œdematous, but scarcely pitted upon pressure. She passed the night badly, owing to the continuance of the gastric pain, and the supervention of obstinate hiccup. The icteroid tinge of the conjunctiva was more marked. She was ordered to suck ice, and ¼ gr. of morphia hydrochlor. was sprinkled endermically, as a blister had been previously applied over the epigastrium. No relief was obtained, and she died early the next morning, after a restless and painful night.

Post-mortem examination thirty hours after death.

Abdomen.—Interior of the stomach universally of a dark livid red, with arborescent vascularity, except near the cardiac end. Along the lesser curvature there was one very thin spot. No thickening nor induration near the pylorus. The pancreas was normal in appearance, but at its head, in the arch of the duodenum, were three or four enlarged lymphatic glands, the pressure of which on the bile duct accounted for the jaundice.

Chest.—The heart was enormously large, and weighed 16¾ oz. when drained of its blood, being thus about double the average weight. The left ventricle was greatly hypertrophied, and the anterior flap of the mitral valve was thickened, studded with numerous warty growths along its free edge, and on its ventricular aspect was a large excrescence, about three-quarters of a inch by half an inch. The aortic valves were incompetent ; each of them ragged, irregular, and covered with warty vegetations. One small patch of atheroma was apparent at the commencement of the aorta. The lungs and other viscera were healthy.

The main point this case illustrates is the comparative latency of the heart mischief, and the concentration of the patient's sufferings and complainings on the stomach, the symptoms referable to which were so entirely secondary and independent of any organic lesion in that viscus.

Literature.

Chemical Text Books.

We have so often to commend the manuals brought out by Messrs. Churchill, that words of praise seem likely to become exhausted. Fownes's Chemical Manual* has been one of the most favoured from the beginning, and its successive editors have endeavoured to keep it worthy of the position its author first gave it. The tenth edition, now before us, is edited by Dr. Bence Jones and Mr. Henry Watts, names that are a sufficient guarantee that it will remain a safe guide. The first thing we observed was increased thickness in our old text book. It is increased in size about 20 per cent. We are not sure that this is a recommendation, all the volumes seem to grow more bulky at every succeeding edition. We presume that in the case of chemistry this has been found quite necessary. It is easy to imagine the difficulty of restraining the limits of such a work. The chapter on Chemical Philosophy seems to have been entirely re-written, and some parts of it are entitled to praise for their clearness. It is of course in Organic Chemistry that the greatest changes have become necessary, on account of the rapid progress of the science. Still there are some important additions to and changes in the earliest part of the work. It is proper to announce that this edition has been adapted to the new notation, and we may add that the metrical weights and measures have also been introduced, comparative tables being given for the use of those who need them.

From America we have a carefully prepared Manual of Inorganic Chemistry† by Professor Eliot and Storer. It is issued in London by M. Van Voorst, and will be found of service to many students. Much trouble is taken by the authors to illustrate and explain the principles of this science, and full directions are given to the student to enable him to perform the experiments which illustrate these principles. This is a much better mode of instruction than merely compiling the descriptions of the substances, and the student who confines his attention to *inorganic* chemistry will be thankful for Prof. Eliot and Storer's book.

Mr. Kay-Shuttleworth is the author of an elementary work‡ which we may commend to the beginner. The book adopts of course the new notation, and is, to some extent, founded on Prof. Frankland's course of instruction at the Royal College of Chemistry. In a future edition we hope the author will carefully revise his book, as we find here and there statements which we feel sure could not have been gathered from Prof. Frankland's lectures, and which that gentleman would be very sorry to have fathered upon him. This shows the great difficulty experienced by those who are not thorough masters of a subject gathering from those who are principles for the guidance of others. Too often the pupil misunderstands the teacher, and we question altogether the necessity or propriety of a work thus produced. There is no lack of books on chemistry, and those who are preparing for any of the preliminary examinations may easily find a safer guide than this.

Uterine Therapeutics.*

In the present day there is no fear of any dearth of books on diseases of women, a branch of our art which has been pursued with great ardour by many, but unfortunately has been disgraced by a greater amount of quackery than any other. Dr. Tilt has made a stand against the tendency to mere mechanical treatment which deserves our thanks; he sets out in his treatise the value of medical as distinguished from chirurgical treatment, and shows that manual dexterity, however useful, will not suffice for the physician who desires above all things the welfare of his patients. We would not be understood as averse to surgery in proper cases, but we do wish to record our protest against the excessive faith in *local* disease and *local* remedies, which has done much to injure our profession in the eyes of all right-minded men, and by means of which some have preyed upon the public in a manner only exceeded by the vilest quacks.

It is satisfactory to see a work like the one before us reach a third edition, and so need no commendation from us, and we hope that the author's success will lead many to follow in his wake. We have not the least doubt that the work will always be a favourite one with the general practitioner, who is by no means inclined to pin his faith on the pure specialists. They look for books that recognise their ability to carry out the treatment of the cases under their care. This they will find is the case with Dr. Tilts. They hate the quackery which would set up the application of some local remedy as the highest proof of skill, and ignore the observation and sense which the really enlightened practitioner needs. They will, therefore, be glad that the third edition is, in this respect, as worthy as its predecessors of being consulted. Moreover, many additions and changes have been made, which render it a good example of the present state of uterine therapeutics.

Lateral Curvature.†

This little volume is based upon, in fact consists almost entirely of some lectures published by Mr. Barwell in a contemporary journal. It is well known that Mr. Barwell is at issue with most of the other leading orthopœdists both as to the causes and treatment of those diseases to which he has devoted so much of his attention. It is not for us to judge between these gentlemen. Our author is well able to set forth his views, and to say what can be said in their favour. He attributes an influence to the *serratus magnus* in the production of curvature which is not recognised by authorities. He is a great enemy to many orthopœdic appliances in common use, and believes that most satisfactory results may be obtained without the complex apparatus, of which he exhibits a "holy horror." He admits the value of gymnastics in slight cases, and this leads us to remark the little use made of gymnastics in this country. On the continent no education is complete without a proper gymnastic training, and many slight cases of deformities are entirely treated by the professors of gymnastics under the direction of the physician. It is a question whether we might not take a leaf from our Continental brethren in this respect.

Letts' Diaries for 1869.

Two handy sized, firmly bound, and decidedly useful books. One, "Letts' Medical Diary," the other, "Letts' Appointment Diary," deserve a passing notice, and the attention of the profession. The former of these diaries (Letts' Medical) contains, not only the usual daily visiting accouchement and vaccinating lists, but also a well compiled mass of information, very important to be within our reach sometimes, and consists of—Almanack, Ready Reckoner, lists of Army and Navy Agents, University Terms, Banks, Birthdays, Chronological Notes, and the Jewish Kalender, also Sunday Lessons, Directions for Will-making, and Domestic Animals' Breeding Table.

"Letts' Appointment Diary" contains much that is found in the other book, besides a mass of information not less noteworthy than the other.

Letts' Monthly, or Professional Diary is a very unpretending little work, comprising the twelve months, each stitched in a separate section, so that the current month may be carried in the waistcoat pocket for every day use, without the necessity of taking what one may not at present require. These sections are encased in a neat wallet, with a small cloth cover, which acts as a commercial memoranda, and a wrapper for each month to prevent rubbing in the pocket. The ruling adopted is a day to each page for notes and cash, which will be found very useful to, and sufficient for, those who do not care to be encumbered with the more bulky editions published by the same firm.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

December 21, 1868.

Dr. Richardson, F.R.S., President, in the Chair.

Mr. **Francis Mason** exhibited a patient on whom two years ago he had performed Pirogoff's operation for partial amputation of the foot. The stump was very satisfactory. The patient was now accustomed to walk at least ten miles a day.

Mr. **Maunder** thought it doubtful whether in cases of this operation performed for disease, the os calcis did not become carious.

Mr. **Adams** quoted a case in which the operation had been performed nine years ago upon a patient with incipient pulmonary tubercle. The reparative process was perfect, and the patient now had an excellent stump. The form of operation, provided the os calcis was not involved, was the best extant.

Mr. **Bryant** said that this operation, which left nature's own pad upon that portion of the stump subject to pressure, was the most convenient of all. The objection as to the tendency to return of the necrosis was equally applicable to all partial amputations.

Dr. **George Buchanan** read a paper on local conditions affecting the distribution of phthisis. After a review of the general subject of the climatology of phthisis, the first important contribution to which was Sir James Clark's monogram to Dr. Archibald Sims in 1840, adding much by his observations on mountain climate to the general knowledge. The author traced the steps of the investigation which now seemed to point to the conclusion that dryness or dampness of soil has a marked influence upon the death rate. The tables of the Registrar-General, examined during twenty years, seemed to indicate that in those towns where sanitary improvements had taken place, a decrease in the mortality from phthisis coincided with one kind of change, and one only, viz., where the works constructed for the removal of sewage had had the effect of draining away the moisture of the subsoil. The author exhibited two diagrammatic tables, the first showed the effect of the change indicated upon the death-rate from phthisis in the cases of urban populations. "A" included Salisbury, Ely, Rugby, Banbury, Worthing, Macclesfield, Croydon, and Cardiff; in all these towns there had been much drying of the subsoil, and phthisis had greatly decreased. "B" included Leicester, where improvement had been manifested in a greater degree at an early period after completion of the works than at a later period. "C" included Newport, Bristol, Devon, Warwick, where evidence of drying had not been so complete in them, though the general tendency to improvement was manifest, the results were less complete and more variable. "D" included Merthyr Tydvil, Stratford, and Chelmsford, in which there had been a small degree of drying, with but slight improvement. "E" included cases in which there had been no change of soil. The second table showed the influence on rural populations. It indicated that there was less mortality in cases of dwellers upon impervious than upon pervious soils, and less upon high ground than upon low ground. The general inference from the whole was that wetness of soil was a cause of phthisis in regard to those residing upon it. Collateral evidence in support of the proposition was given in 1862 by Dr. Bowditch in America, and lately by the Registrar-General for Scotland in respect of certain townships in the North.

---

* A Handbook of Uterine Therapeutics and of Diseases of Women. By E. J. Tilt, M.D., third edition, London: John Churchill and Sons.

† Causes and Treatment of Lateral Curvature of the Spine, by Richard Barwell, F.R.C.S. London: Hardwicke, 1868.

Dr. **Gibbon** thought that due allowance had not been made for the improved diagnosis of modern days. Fatal cases had been wrongly classed as phthisis in many instances. Much, too, had been achieved by changes in social surroundings. Two great exceptions occurred to vitiate the rule. Ongar and Sheppey, notoriously wet, enjoyed a great immunity from phthisis. He considered that sunlight was a much more efficient modifying cause of health and disease.

Dr. **Anstie** pointed out the strong evidence in favour of Dr. Buchanan's proposition afforded by the fact of the corroboration of the table (urban) by the other table (rural).

Dr. **Cholmely** said that it was a popular notion in the few counties that, since their drainage, though ague had decreased phthisis had increased. He thought it very probable, however, that this opinion is founded on error.

Mr. **Whitaker** objected to any supposed evidence afforded by Ongar; in this case, though the phthisis death-rate was low, the pulmonary death-rate was high. There had no doubt been errors in the return; furthermore, Ongar was not one of the wet districts; it was built on London clay covered by gravel. Sheppey was an apparent exception to the rule; this is a low lying area bordering on the sea. Sea water has not the effect of land water.

Dr. **Symes Thomson** called attention to the great discrepancies between these conclusions and those presented by Mr. Havil, and the results were diametrically opposed, and seemed to prove the fallacy of figures. He objected to any conclusions drawn from the supposed prevalence of sunlight. He considered the great weight of evidence to be in favour of Dr. Buchanan.

Dr. **Rogers** moved that endeavours should be made to induce foreign observers to test the conclusions in the various countries.

The **President** said there was one arid district where phthisis is unknown. Attention has been lately called to a potent cause of dampness in houses built in late years. Both sea sand and timber which has been saturated with sea salt are commonly used in their construction. This fact is sufficient to be a great cause of humidity, and as St. Thomas's Hospital is being supplied with wood in this condition, the consequences are likely to be serious. Granting that humidity is a powerful cause of phthisis, the great question which remians is, how does a moist atmosphere bring about the result?

Dr. **Buchanan** replied, and the meeting adjourned.

THE SURGICAL SOCIETY OF IRELAND.

The opening meeting for the session of 1868—69 was held on the evening of Friday, 11th December, in the Albert Hall, Royal College of Surgeons.

The President of the College, Mr. **Porter**, delivered the following address:—

Gentlemen,—The close connection that has ever existed between the Royal College of Surgeons in Ireland and this Society, places me, as President of the former, in the position of Chairman this evening.

On the first night of our meeting, or opening of the session, it has been customary for the President to make some remarks; and, believe me, I feel the duty of addressing you a high honour, and at the same time a source of gratification to have an opportunity afforded of thanking many of the members of this Society of having placed me in the proud position, and by virtue of it, in the distinguished post of Chairman on this occasion.

When we look back upon the vast amount of work done by this Society during the many sessions since its foundation, we have every reason to feel satisfied, and congratulate ourselves on its flourishing and salutary condition. Let us hope that the session now dawning, may equal, if not surpass, those gone by in the number and value of the communications. We must ever regard societies like this, which accept and discuss important questions relating to the different divisions of medical science, and publish the various opinions of practical men elicited by free discussion, as among the most potent means that can be devised for the cultivation and propagation of medical and surgical knowledge. The benefits that flow from such a society are immeasurable. We meet to detail each other's experience in a pursuit that is necessarily from its nature continually suffering change.

And let me here remind you that although this Society is called "The Surgical Society of Ireland," we have always had at its *reunions* papers, not only on surgery, but most important facts in medicine, anatomy, midwifery, chemistry, and forensic medicine, brought under our consideration.

Judging from the past, I feel that we may fairly look to the future with the brightest anticipations, and cherish the hope that medical science cannot but flourish whilst under the patronage and fostering care of this Society.

Gentlemen,—I shall not weary you, or waste your time by attempting to explain the many advantages that such a Society confers on our profession, or to enumerate the many interesting and valuable communications that have been made during last session. This Society requires no eulogy from me; it has stood the test of time, and the high position to which Irish Surgery has attained is in no small measure due to the instrumentality of this body.

Within these walls subjects have been discussed, and doctrines enunciated, that have shed unfading lustre upon Irish surgery. Here Bellingham and others declared to the professional world that aneurism could be cured without the knife. Here Butcher presented the proofs of successful resection of the knee-joint, an operation that had been long neglected and almost forgotten in this country until he revived it. Here L'Estrange exhibited the many improvements in those instruments which bear his name, and materially aid the operating surgeon.

Papers of the greatest value have been sent forth from its meetings, and names that will last as long as letters endure have been inscribed on the roll of its membership—men who in their time were looked upon as giants in the profession have handed down this Society to us. It should be, and I feel convinced will be, our utmost ambition to uphold unsullied its fair reputation.

The hospitals of this city, and those of the provinces, contain cases of incalculable value; and in passing let me express my regret that our country members do not come more frequently among us, or favour us with papers; rich stores of information are deposited in the minds of our provincial *confrères* which we would gratefully accept. Vast is the advantage that flows from the interchange of knowledge among the members of our profession, and there is no place in the world, I am proud to say, where more kindly feeling exists between the staffs of hospitals than in Dublin—a fact which in a great degree explains the unabated success of this Society. A generous and friendly feeling pervades our meeting, and but one object kept in view—namely, to arrive at truth.

Gentleman,—When speaking of the success of this Society, I should be unjust indeed if I did not bear testimony to the important services of our respected Honorary Secretaries, Drs. Benson and Richardson. These gentlemen give up a large portion of their valuable time to the working of the Society, and as a member of Council I can state that their offices are not sinecures. We are much indebted for the interest they take in the progress and welfare of our Society.

To the Council of the Royal College of Surgeons our best thanks are also due, not only for the favour of allowing us to hold our meetings in this magnificent hall, but also for the substantial aid annually afforded us.

Our grateful acknowledgments must in addition be tendered to the Editor of the **Dublin Medical Press and Circular**, for the generous manner in which he publishes our proceedings, thereby increasing the usefulness of this Society.

Gentlemen,—As years roll on, in a large body like this, blanks must occur in the list of its members. I had hoped that it might have fallen to my lot to announce that we had not suffered in this respect; but I regret to say, since last we met here, we have been deprived by the hand of Death of two distinguished members; I allude to Dr. Samuel Little Hardy, and Dr. James Whitelaw Stronge.

Dr. Hardy was a regular attendant of our meetings, and was the contributor of two highly important communications on the Local application of Chloroform Vapour; the first he read on the 8th April, 1854, and on the 10th February, 1855, he gave an account of the results of the local application of chloroform vapour in the hands of members of the Society, and others.

It may be stated with sincerity that the profession, in him, has lost an accomplished physician, and this Society, a warm friend.

Doctor Stronge was elected a member of this Society on the 19th April, 1866, so that he was rather a junior member, and although he had not made any communication here, I know that it was his intention, had he been spared, to be regular in attendance upon our meetings, and give us papers from time to time. He was a highly informed man, and had the happy power of imparting his knowlddge to others in a most impressive manner. The profession has lost in him an ardent worker and a thorough gentleman.

These sad changes must, of course, take place as time advances; but we should not repine, hosts of young and energetic men are continually springing up to fill each gap, and I feel confident they will maintain unimpaired, that which shall be handed down to their care.

SYPHILITIC DISEASE OF LARYNX.

Mr. **John Morgan** exhibited a specimen of syphilitic ulceration of the larynx, and observed that death having occurred within the previous week, he thought the members of the Society would derive some interest from the inspection of the specimen. We propose giving this important case in our next number.

CANCER OF THE MALE BREAST.

Professor **Hargrave** exhibited a specimen of cancer taken from the male breast. The subject of the disease was a man forty-five years of age, and the tumour had been removed last Monday by operation. He suffered from pains in the bones and in the fibrous structures for the last twelve or fourteen years.

The tumour commenced as a small tubercle just at the sternum, and increased slowly and gradually. He derived some apparent benefit from the internal use of hydriodate of potash. He was in the habit of applying the butter of antimony, after he had first placed a hot poultice on the tumour. When in hospital he experienced very little pain; the only place in which he had it was at the upper part of the sternum, and by the application of a few leeches it was relieved. He (Professor Hargrave) confessed that he did not expect the great quantity of arterial hæmorrhage which took place. There was also a good deal of venous hæmorrhage, which was promptly arrested. When the tumour was removed he made a section in its posterior part, which presented the most decided appearance of cancer. Dr. Barker, who had made a microscopic examination of the section, reports that it consisted of cancer cells and cancer juice. Up to the present time the man has been getting on well. The wound is suppurating, and healthy granulations are forming. Professor Hargrave also exhibited a cast showing the appearance and colour of the tumour before removal.

TYPHOID ULCERATION AND PERFORATION OF INTESTINE.

Dr. **Hewitt** brought under the notice of the Society a case of typhoid fever with ulceration and perforation, which had been under his care in the City of Dublin Hospital. The patient had been treated with strong drastic cathartics before she was admitted to hospital. All the symptoms of typhoid fever were present. She had the usual spots with tympanitis, tenderness, and gurgling, up to within a few hours before death. She did not exhibit any symptoms which could be called unusual from the time of her admission, on the 11th of last November, when she had been eight days ill, until the evening of the 5th of December, when she became very sleepless and very delirious, with remarkable weakness of the circulation, so that the action of the heart was exceedingly like what Dr. Stokes compared to the fœtal heart. At the time he first saw the patient, he could hardly distinguish the sounds of the heart, and for days it was like the tick of a watch. The diarrhœa was not at all alarming; it always ceased after a very few doses of a combination of sulphate of copper and opium, and at no time was it exhausting. At the close of the third week the temperature became normal, and continued so for three days. At this time she craved for meat, but he refused to give solid food. Two or three days afterwards her tongue became brown and dry; nevertheless, she complained of neither tenderness nor pain in the abdomen, and she could bear even deep-seated pressure on the ilio cœcal region. The tympanitis disappeared, and no prominent abdominal symptoms were then present. That day week he saw the woman, and from her great debility, the brownness of the tongue, and the want of reaction, he became convinced there was latent mischief going on in the intestine. He ordered a blister to be put over the ilio-cœcal region, and she expressed herself better. On Saturday night she complained of a sudden pain, accompanied by distressing vomiting and purging. All through Sunday the pain increased and became general over the abdomen; vomiting also continued, notwithstanding the use of opium, and on Monday morning, when he was on duty in the hospital, he was told that the poor woman had expressed a sudden fear of death; but in a few moments, and before he could attend her, she had died. He apprehended that peritonitis had set in on Saturday night, and that probably perforation had taken place on Monday morning. Twelve hours after death the *post-mortem* examination was made. They found the intestines unusually congested. In the upper portion of the ilium, some distance from the iliocœcal region, he found the oval ulcers referred to by Murchison. He also found Peyer's patches in a state of slough, having a dirty yellowish appearance and extremely fetid smell. As he proceeded with the examination of these, he discovered the perforation, and they would see the remains of the lymph caused by the process. All the intestines were glued together. A large quantity of straw-coloured fluid, with recent lymph, filled up the cavity. The iliocœcal valve was greatly ulcerated, and in a semi-gangrenous condition. The solitary glands in the cœcum, and the ascending colon likewise, were extensively ulcerated. This case, in connection with the remarkable latency of the symptoms, was, he thought, worthy of the attention of the Society. It was a result which they must always fear in typhoid fever. Although the heart was a small one, and had a great portion of fat on the upper portion of the right ventricle, it exhibited in no degree the kind of softening found in typhus fever. The perforation was somewhat larger in size than a split pea. Even if the woman had escaped perforation at this point she ran the risk of it in others of the diseased Peyerian patches.

(To be continued.)

DUBLIN PATHOLOGICAL SOCIETY.

December 12th, 1868.

Dr. McClintock in the Chair.

Dr. **Bennett** exhibited an ovarian tumour which he removed two weeks previously from a patient, who died in Sir Patrick Dun's Hospital. The history of the case was as follows: Before last Christmas she had her last confinement, and immediately afterwards noticed the tumour for the first time.

The earlier period of its growth was attended with considerable and constant pain over the whole abdomen. In February last, she came into the Whitworth Hospital, under the care of Professor McDowell, by whom she was tapped, she remained in hospital about five weeks, and then returned home. Six weeks afterwards she was admitted into Sir Patrick Dun's Hospital, where she continued during the greater part of the summer, while there she was tapped three times, and on each occasion some difficulty was experienced in drawing off the fluid which was of a sero-purulent character.

Dr. McDowell and he agreed that it was not a suitable case for operation as there appeared to be constant peritonity going on about the tumour.

In September he was asked to see the case by Dr. Kennedy, when he found an abscess pointing at the scar of the last incision. He concluded that one of the cysts had suppurated, and was tending to open externally. After a few days a small opening formed which gave vent to a large quantity of pus. During the next two days serum and pus flowed alternately from this opening. The tumour then subsided a little, and he was in hopes that the cyst would have become obliterated, and in order to facilitate this he put a compress on the abdomen, but failed to make the tumour smaller. In about ten days the character of the tumour changed, and from being dull on percussion it became tympanitic, owing to air having entered through the opening. A probe could now be passed into the tumour towards the pelvis, but not in a lateral direction, owing, as the *post-mortem* examination showed, to the projection of secondary cysts into that which had suppurated. The woman sank from hectic.

On opening the abdomen there was great difficulty in separating the cyst from the abdominal parietes to which it was universally adherent in front. And all along the left side, above and laterally, it was connected by old adhesions to the principal abdominal viscera.

Posteriorly the tumour was but slightly adherent. The opposite ovary was also diseased; it was replaced by a small cystic tumour composed of two chambers, the whole about the size of a small hen's egg. The cyst full of clear fluid glistening with cholesterine, and the cyst well coated with a fine layer of bony matter on the interior. The larger ovarian tumour was an instance of the second variety of multilocular ovarian cyst described by Hodgkin, in which the secondary cyst projecting into the cavity of the principal asissile on its wall. The contents of the cysts were in this case very various, some containing a viscid slime, others thin fluid and cholesterine, and the principal cyst pus and air.

Dr. Bennett exhibited a tumour, which he had removed in the dissecting room, and which he thought worth showing as presenting a marked contrast with the ovarian tumour to which he had just directed attention, as well as from some points of pathological interest of its own. This was a fibrous tumour of the uterus, of that variety which projects into the abdominal cavity, and which has so great a tendency to assume the pedunculated character, which this specimen presented. The whole surface of the tumour was covered everywhere by secondary tumours of various sizes, and shapes, and of which those lying lowest down in the pelvis were most fully detached. This tumour was perfectly moveable in the abdomen. The cause of this mobility was found to be the great elongation of the vagina and uterus, which latter was narrowed and elongated to more than double its normal length.

The structure of this tumour was composed of fibrous tissue curled up in irregular bundles, and with a tendency to separate. The point of greatest interest was the arterial and venous supply of the tumour which was unusually large in calibre. There were two arteries almost as large as the brachial vessels, passing into the base of the tumour, and the section of the lower part; exposed a structure resembling the sinuses of a pregnant uterus. So great was the quantity of venous blood contained in this tumour, that on removing it a large quantity flowed into the pelvis, the chief points of interest were the elongation of the uterus which constituted the pedicle, the existence of the great arterial trunks going into the base of the tumour, and also the veins which it contained. The ovaries were normal. The point of most interest in a diagnostic point of view in comparing this tumour wfth a multilocular ovarian cyst was the free mobility of the secondary tumours on the principal mass, a condition resulting from their exoginous growth, and which contrasts strongly with the fixity of the lobules of an ovarian tumour in relation to the mass of the tumour, a necessary result of their endoginous growth.

The points of interest in reference to operative proceedings are, that a fibrous tumour though freely moveable is more closely adherent to the uterus, and may have the uterus as an elongated pedicle attached to it, and lastly, it may possess an enormous vascular supply.

The case which Dr. Lyons brought before the notice of the Society was one of abscess of the liver. A woman, aged fifty-six, was admitted to the Whitworth Hospital in the month of September, she had always enjoyed good health, until about four years, when both she and her husband left this country and settled in New York. Her husband died there, and she determined to return to Ireland, after a residence of nearly four years in America. During all this time she continued in her usual health, but on her return voyage, as she neared Queenstown, she had repeated attacks of nausea, which lasted several days. On her arrival in this country she came to Dublin and was admitted into the Whitworth Hospital. At that time she had a peculiar haggard, worn look. The conjunctivæ was of a pure pearly white, but there was no appearance of jaundice or any coloured tint. She suffered from distress in the stomach, but it was of an intermittent character, and ill-defined in situation.

It was sometimes very severe and of an oppressive character, but on the other hand she would be for days without any pain. Her pulse was very quick never below 90, and occasionally ranging as high as 100 or 120, but one of the most important features of the case was the frequent recurrence of rigors. New rigors would take place several nights in succession; when they would cease altogether and then would be an apparent improvement in the symptoms, but they would come on again in a few days, followed in many instances by copious sweating. After taking all these circumstances into consideration, Dr. Lyons came to the conclusion, that this was a case of abscess of the liver, for although there were not any symptoms to point to the liver as the main seat of the disease, yet, from a consideration of all that was presented in the case, and the frequent recurrence of rigors, he had no doubt that the woman was labouring under that disease. After this for a fortnight or three weeks the patient was able to sit up and expressed herself as feeling much better, when there was a renewal of the old symptoms, and the rigors returned accompanied by sweats of a very exhausting character. She gradually succumbed and died, after two months' residence in the hospital.

The *post-mortem* examination proved the truth of the diagnosis. On opening the cavity of the abdomen a very large abscess became apparent, which occupied the right side of the liver, and was just on the eve of bursting into the peritoneal cavity. His friend Dr. Foot had made a most careful examination of the liver, and found that there was not only a large multilocular abscess, but that there were at least three other abscesses of considerable dimensions, Dr. Lyons then pointed out the special features and position of these abscesses.

The origin of abscess on the liver is very obscure, and this case throws no light on it. They know that persons resident abroad and becoming affected with dysentery sometimes became, by secondary absorption through the walls of the intestinal canal, attacked with abscess of the liver.

It was not so in this case. It was a remarkable fact that the bile seemed secreted of a tolerably healthy character and in sufficient quantity, the gall bladder containing a fair amount of bile, and there was no acteroid tinge present, during the woman's residence in hospital.

Dr. Lyons had, within a period of three years, seen no less than twelve cases of abscess of the liver, and in only one of them was jaundice present.

The special interest connected with this case was as to its diagnosis. He could not say what was the mode of origin of the disease in this particular instance. And in that respect it resembled many other cases of hepatic abscess, in which it was impossible to discover the point of departure of the morbid powers.

BLANCHING OF THE HAIR.

A paper read before the Royal Society by Mr. Erasmus Wilson, has thrown new light on the question as to what causes the sudden whitening of the hair, often produced by fright or profound grief. He cites a case in which the hair was coloured white and brown alternately from end to end. The white segments were about one-half the length of the brown, and the two together measured about one-third of a line. Under the microscope the colors were reversed, and it was obvious that the opacity of the white portions was due to a vast accumulation of air globules packed closely together in the fibrous structure of the hair, as well as the medulla. There was no absence of pigment, but the accumulation of air-globules veiled and obscured the normal colour and structure. Mr. Wilson suggested the possibility of the brown portion being the day growth, and the white portion the night growth. He also said, in reference to the sudden blanching of the whole hair, of which there were many cases on record, that during the prevalence of a violent nervous shock, the normal fluids of the hair might be drawn inward towards the body, in unison with the generally contracted and collapsed state of the surface, and that the vacuities left by this process of exhaustion might be suddenly filled with atmospheric air. An interesting discussion followed the reading of the paper, Dr. Sharpey alluded to a recent case of sudden blanching of the hair reported by Dr. Landois, of Griefswald, in *Vichow's Archiv*, which was ascertained to be the result of an accumulation air globules in the fibrous substance of the hair.—*Phil. Med. and Surg. Rep.*

Consanguineous Marriages.—M. Voisin states as the result of a careful examination of 1,077 of his patients at the Bicêtre and Salpétrière, that in no one instance of his idiotic, epileptic, or insane patients, could healthy consanguinity be legitimately regarded as the cause of the affection. He believes that the ill results which have been observed after consanguineous unions are not really due to these, but are to be attributed to the ordinary hereditary causes.—*Union Med.* October 3, 1868.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 6, 1869.

PAUPERISM, CHARITY, AND POOR-LAWS.

How disheartening it is to be obliged to confess that the subject of Pauperism is now the most pressing one of the moment. Alas! for all our dreams of progress and the universal happiness of mankind! Here we are in the beginning of the year 1869 in a position of such gravity with regard to the questions above referred to, as perhaps our history, as a nation, can scarcely parallel. A million of paupers in a wealthy state like this is evidence of the sad want of thought exhibited by those who have preceded us. There has been a great unwillingness to face the difficulties of the question, and hence to us unhappily has been bequeathed the sorrowful task of combatting a perfect sea of human misery and degradation. We have, for instance, before us a pamphlet, written by Dr. Stallard, from which we would select one or two facts to show what are the evils which we have to attack. On January 1st, 1858, there were in the Metropolis, 77,660 paupers relieved, and in 1868 this number had actually swelled to that of 163,179. In the unfortunate district of Poplar there were in 1858 2,874 persons in receipt of relief, and this has swelled to no less than 9,996 in 1868. In Whitechapel, likewise, the numbers relieved on January 1st, 1858, was 2,223, and in 1868 5,266 in a population which has not much increased in numbers. In Bethnal Green in 1841 the expenditure for the poor-rate was only £15,989, whereas this year it is £55,260. "I venture to assert," says Dr. Stallard, "without fear of contradiction, that there is scarcely a native male adult in Bethnal Green who is fit for military service. There are here hundreds of men who, being fit only for children's work, earn children's wages. Nowhere is the standard of comfort so low. Furniture is often thought superfluous, and it is a matter of common experience to find a widow trying to rear her family without applying to the parish on earnings which do not amount to twopence per head per day." Take the account, too, of the frightful overcrowding which is so common in the East-end and in St. Giles's. In a report of a deputation which waited on the Duke of Marlborough at the Privy Council last year, on account of the "Artizan and Labourer's Dwellings Bill," one of the speakers, Mr. Nisbet, said that in one district in St. Giles's there were 600 families, and of these 570 occupied but one room. He had seen one old man, one old woman, and two unmarried persons, who lived together with their children, all occupying one room. One room that had been visited was 12ft. by 13ft., and 7ft. 6in. high. In that room eight persons lived, and the rent was four shillings a week. Another room was 13ft. by 5ft., and 6½ft. high. The father, mother, and five children lived in that, and the rent was four shillings a week. No words could express the wretchedness and filth in which the people lived.

And all this, be it remembered, is taking place, not in Connaught, nor in the uncivilised parts of France or Spain, but in the midst of our boasted civilisation—in London, the centre of industry and freedom. Truly the wisdom of our forefathers has left us in a sad mess, from which all the science at our disposal is required to extricate us. We do not think that it will be necessary for us to quote at greater length the details of the misery with which, alas! all who are members of the medical profession are but too well acquainted. The physician or surgeon to a public charity in the East-end is but too conscious how many of the unfortunates who crowd the consulting-rooms are living in a way which forbids him to hope for any of his directions as to food and other hygienic appliances being attended to. The condition, then, of many of us in this era of the world is still a most melancholy one. Man, of all animals, seems alone to be able to attain an extremity of misery, without having sufficient intelligence to look his fate fairly in the face, or to die, as the lower animals do. Traditions of modes of looking at our tenure of existence, derived from the sad days of human ignorance and superstition, still obscure a clear view of the fact that man is no exception to the rest of animated nature, in his being subject to the evils caused by the "struggle for existence," if he imitates, as he does constantly, the lower animals, in engendering a far greater number of offspring than can be fairly maintained by the provisions and capital at hand. Mr. Malthus, at the beginning of this century, so clearly showed the truth of this proposition that it is now held to be axiomatic by all who have ever seriously examined this branch of science. Of course we must not expect the prejudiced, or the aristocratic members of society, to attend to such commonplace and vulgar accounts of the origin of poverty as this. A well-known contemporary of the *Medical Times and Gazette*, indeed, in commenting on some bold and admirable remarks recently made in the Dialectical Society by Lord Amberley, Dr. C. Drysdale, and others, would not hear of us being over-peopled. Conservatives such as he never will. They are too well satisfied with things as they are to wish to see them altered, and hence go in for large families, primogeniture, entail, &c., &c. Let them! It is the interest of many persons that the people should be poor, since they can buy their services more cheaply. Such persons, of course, belong, or think they belong, to the higher classes, whom it is the duty of the others to serve as cheaply as possible. But to all true lovers of the human race, the poverty and distress of the poor is a subject of never-ceasing pain. And the present misery and pauperism of Poplar and Whitechapel would be indeed a blessing to the poor if it should render the subject of poverty a popular one, to be discussed until such a curse be made to disappear from the face of civilisation. The immediate and pressing question, of course, for these pauperised districts, is how this winter is to be passed without an utter bankruptcy of the district. Eventually, we doubt not that London will, as Mr. Mill proposes, be turned into one city for the purposes of rating to the poor's rate. It is iniquitous that the inhabitant of the rich quarter of St. James's should be so slightly taxed for the poor in comparison with his poor neighbour of Poplar. Were he taxed he would give, it is presumable, a little more attention to the great subject of poverty. At present, all but the best minds among the educated and richer classes, almost ignore the subject. It is, they say, so difficult and disagreeable! We would suggest that all funds subscribed for the maintenance of the poor in Poplar on this trying occasion, should be, as far as possible, employed as wages; and that the inhabitants should be employed in raising better dwellings for the labouring classes, in cleansing and beautifying their dull neighbourhood, and making it more fit for the habitation of a happier race than has hitherto peopled it. We are opposed to spending the funds on emigration. That bubble, we conceive, has burst. We have sent out our millions during this half century. Are our wages any better now? Are our profits any higher? Are we less crowded? The above testimony says no. Has the large family system been enough discussed? In this, we apprehend, lies our hope for the future.

◆

THE SANITARY STATE OF CALCUTTA.

If, as most men are now ready to admit, the condition and prospects of our Eastern Empire deserve the attentive consideration of our greatest statesmen, medical men may think that the improvements that have been introduced in the sanitary state of its capital are worth their brief consideration. Those who lately have been in India do not need to be told that much has been attempted. Many, however, who have no personal interest in the matter, are apt to regard pictures of what was as indications of what is. It may, indeed, be open to question whether, ever since our possession, there has not been a steady, though a slow, progress. Comparing the data that can be obtained at considerable distances of time, those who think so have certainly much to say in proof of the correctness of their opinion; though, on the other hand, there are facts that they would find it difficult to harmonise with their views. Be this as it may, no one can compare the condition of the Calcutta of to-day with that of a generation ago without admitting the immense strides that have lately been made, and feeling thankful that our later rule has been marked with so much real improvement.

The "City of the Palaces" has been drained, better water is drank, the European inhabitants live more rationally, the jungles are no longer so near, and many other things have resulted in an improved death-rate; and the same may be said of other cities where we have attempted to discharge this high function of such a government as ours. The statistics of the capitals of the three Presidencies, down to the latest returns, are as follows:—

	Population.	Mortality per 1,000.	Receipts.	Expenditure.
Calcutta in 1867—			£	£
Municipal ...	430,000	28·08	263,114	257,318
Suburbs (about)	500,000	—	—	—
Hourah (about)	80,000	—	—	—
Bombay Island in 1865	816,562	35·4	174,551	—
Madras in 1866-67	450,000	30·8	40,755	45,443

The large number of new streets, consisting of really handsome houses, each with its own garden, that have lately been completed, have contributed both to the beauty and health of the quarter in which they are situated. This is the most remarkable quarter, and is sure to attract the first attention of new arrivals. Scarcely anything offensive is here to be found—not nearly so much as is to be met with in Paris and other Continental cities.

A little beyond, however, there is another division where sanitary measures have yet to be attempted, and where filth and disease triumph. The drains, if such they may be called, are open to the tropical sun, and the attempt to stir them up gives rise to pestilence. The lowest and worst of the population dwell here, and perish in frightful numbers. It is a city of filth and vice, where epidemics are endemic. Yet there is hope even for this quarter. Already a determined effort to infuse new life into it by sanitation is being made, and in a couple of years it will be drained and have a good supply of water. Mr. Stuart Hogg, of the Civil Service, is the Commissioner who is entrusted with the great undertaking. He and his staff merit full confidence from the manner in which they have carried out the works in the European part, and no doubt will do here. The costs must be great, but the money will be profitably expended. The ground is of great value, often fetching prices which only London and Paris can compare with, and thus it is likely that the investment may be a fair one, in addition to the destruction of disease which will be effected. It is much to be regretted that the Zemindars do not see the value of sanitary measures, and too often do all in their power to oppose them.

Drainage and water-supply—these are the two essentials of healthy cities, and on these the greatest energy is now being concentrated, so that it is hoped a complete purification may be effected, and the whole city of Calcutta made worthy of its position as the capital of our Indian Empire.

From a recent letter of the correspondent of the *Times*, who seems to have thoroughly informed himself as to the facts of the case, we take the following details:—

"At the cost of somewhat more than half a million sterling, lent by Government to the municipality, the Hooghly water is to be filtered, conveyed for eighteen miles from Phulta, above Barrackpore, and supplied to the city at the rate of 6,000,000 gallons a-day. The works will be finished by this time next year. The water will be supplied to the third storey of English houses, and by numerous stand-pipes in the native city—a mode rendered necessary by native prejudices. The effect of this vast consumption of pure water directly on the people, and indirectly through the drainage, need not be pointed out. The drainage works are magnificent as far as they have gone. Like all deltaic rivers, the Hooghly is rising its bed, so that the drainage must be away from the river. Fortunately, there are low lagoons to the east, known as the salt water lakes. They have a slight connection with the sea, but it is designed ultimately to reclaim a large portion of them by the sewage of Calcutta. Already one mile has been embanked, ready for the first experiment. Mr. Clark, the municipal engineer, accordingly planned a series of great drains, like the Cloaca Maxima, where it still may be seen on the Tiber shore, meeting outside of Calcutta, whence the sewage is to be pumped up to a higher level, and is allowed to flow to the salt lakes. To drain all Calcutta would cost nearly a million sterling, but it has been decided that the underground drainage shall stop at two-thirds of the city, including the most repulsive portion in the centre, and that the remainder of the native town shall have surface drains well flushed. The drains are completed all over the European quarters, and the outfall works for the whole city are nearly finished, at an expenditure of £450,000. The scheme will involve some £150,000 more, and to raise the funds the house-rate has just been increased to ten per cent., the native Justices to a man voting against the addition. Nothing can be finer than the two great drains and the outfall works. There is to be a third great drain, and the three meet at the outfall works in some splendid tunnelling, which would accommodate a single line of underground railway. The doctors have raised two difficulties as to the danger of semi-solid sewage in underground drains in a tropical city, and as to the evil of voiding the sewage at a spot whence the prevailing wind for a third of the year will blow the noxious exhalations back upon the city. I confess that until going over the works in Calcutta, and lately inspecting the drainage works between Edinburgh and the sea, I shared both apprehensions. But the experimental drains are working admirably, and though the time is at hand when they must receive all night-soil, the new waterworks will be added to the effects of a rainfall of seventy-five inches a-year. The solid sewage is conveyed by trains along the Municipal Railway, which skirts the circular road side by side with the Maharatta ditch, six and a-half miles to the salt lakes. It is impossible to doubt that that and the discharge of the drains will speedily convert the shallow lagoons, carefully embanked in portions to exclude the salt water, into the finest rice land, if not kitchen gardens. Even at Lahore the natives alone have made a similar system such a success that, for the first time in India, manure has come to possess some value."

◆

Notes on Current Topics.

Lady Doctors and the Competitors for their Patronage.

The British Lying-in Hospital and Dr. James Edmunds, the Female Medical College, the insult to Dr. Eastlake and the Profession, and all the ingredients of the dirty mess whose unfragrance pervaded the medical nose some months ago, have got a fresh stir, and this time the befoulment of the nest offends the public as well as the professional nostril.

Dr. Thomas Snow Beck has been shaking up Dr. Edmunds, and Dr. Edmunds has been stirring up Dr. Beck, and both have been raking up the British Lying-in Hospital and the Female Medical College, and the aroma has spread through the London police courts to the public sense and the fragrance of the Profession is immeasurably damaged.

Our fingers are not dirty enough for the manipulation of the mess, and we decline to touch it, simply remarking as we did on the former occasion, "that it affords a cogent warning to the Profession not to place themselves in the position of alliance with the administrators of the establishment."

Strike of Tenor Singers.

The limits of action of the human larynx has at length been practically marked by a strike on the part of tenor singers against the orchestral conductors who have the regulation of concerts.

There has existed for many years an arbitrary pitch altogether out of the reach of all private singers, and, it would appear, also beyond the capacity of the most perfect vocal development. Thus almost all the operatic music written for the tenor or higher male voice has been obliged to be retranscribed or transposed down to bring it within the scope of ordinary performers. This in the case of orchestral performances is impossible, and tenors have been obliged to screech up to the pitch to the great injury of their voices, and to the loss to their performance of that richness and sweetness which belongs to the middle register of the voice.

There is really no reason whatever why music should be sung in an unattainable key, and the tenors, headed by Mr. Sims Reeves, have absolutely refused to injure their voices or depreciate their performance to please the fancy of conductors.

The Sacred Harmonic Society, who adhere to the old pitch, will have to do without Mr. Sims Reeves, and already the lower grade, known as the French pitch, has been adopted for forthcoming concerts.

Registry of Deaths.

The nomenclature lately recommended by the committee of the London College of Physicians, has been adopted as far as the designation of fevers is concerned. The English Registrar-General has issued a notice that medical practitioners are requested to use the names, in order that the Registrar-General may distinguish the several forms of fever in the returns of the ensuing year.

The committee, it will be remembered, detailed four forms of fever—typhus, enteric, relapsing, and simple continued fevers.

Slanders on the Profession.

The office of Vindicator of the Profession from the slanders to which it, as well as other bodies, are liable is not an agreeable one, and it has been uniformly shifted by licensing corporations from themselves to the Medical Council, and by that cautious assembly back again, till at last the profession has had to act for itself, and by means of its protective association to give expression to the disclaimer which councils and corporations did not care to trouble themselves with.

We don't pretend that it is the duty of licensing corporations to take up the cudgels and drive out every snarling cur which disturbs the profession by his yelping; but there are occasions when the adoption of a resolution would do all that is required of them, and when the slander would be within their dignity, and even in such cases the mouthpieces of the profession show themselves careless or over timid.

It would seem that a statement published in the public press, and reiterated as a literary curiosity all over England, to the effect that "the Governor of Taunton Goal had had applications from members of the profession for the office of Hangman," would have been worthy of notice, not in the form of a denial, which would only enhance the insult, but as a censure on the editors who gave publicity to so obvious and so insulting a lie.

Dr. Carey, of Taunton, an old member of the College, who felt himself aggrieved by such a suggestion, called, last week, the attention of the Secretary of the Royal College of Surgeons of England to it, in a letter which appeared in our last, and received the reply which we append:—

"Royal College of Surgeons of England,
London, W.C.,
29th December, 1868.

Sir,—I have to acknowledge the receipt of your letter of the

26th instant, and accompanying copy of the *Somerset Gazette* of the same date, and I have to acquaint you that, irrespective of the fact that the paragraph to which you allude would appear to be inserted in the *Gazette* upon the authority only of the newspaper reporter, and not of the governor of the prison, it relates to a matter over which this College has no control.

I may add that it would be quite impossible for the authorities of this College to undertake to investigate or contradict every idle statement relating to the surgical profession contained in the columns of the various newspapers published throughout the kingdom.

I am, Sir,
Your obedient servant,
EDWARD TRIMMER,
Secretary.

J. Carey, Esq., M.D.

On this reply, Dr. Carey writes to us :—

"In answer to my letter to the Secretary of the Royal College of Surgeons, London, and published in your last number, calling the attention of that College to a statement going the round of the newspapers that Mr. Oakley, the governor of Taunton jail, has in past times had applications from members of the surgical profession to perform the office of hangman, and calling upon the College, as the natural guardian of the honour of the surgical profession, to take some steps to vindicate that profession from a stigma so revolting, I received the enclosed cool communication from the Secretary, which has dispelled some delusions under which I had hitherto laboured, for I had, until now, imagined that the editor of a newspaper was accountable for the truth of any statement given upon responsible authority in his paper, and that the editor alone knew, when he printed a slander, whether he had it directly from the author, or indirectly from his reporter, and also I used to believe that a member of any respectable London club would be protected against association with hangmen members of that club, and that a public printed assertion made on respectable authority by any respectable journal, that any of the club's members were hangmen, or candidates for the post of hangman, would be properly investigated for the credit of those members that were not—but how I have been mistaken!"

It certainly seems to us that a little over-zeal on the part of the College would be more gratifying to its members than the *laissez faire* spirit in which the matter has been treated; and if the Secretary has not considered it worth his while to say so, we must speak for him, and inform the editor of the *Somerset Gazette* that the falsehood admitted by him to his journal disgraces no one but himself.

Inhumanity of the Police.

AGAINST the universal condemnation which the inhumanity of the police towards the poor woman who last week attempted suicide has brought upon them, they can offer no plea of doubt as to the nature of the case. Even the police must know that to carry a prisoner on a stretcher with nothing on her but a wet shift and a sack thrown over her is brutally inhuman, and to leave her half-drowned and half-frozen for a whole night in a damp cell savours either of stupid carelessness or official cruelty.

We endorse every word of the verdict of the jury :—"That the police were culpable for not calling in the divisional surgeon, and leaving her in a cell the whole of a night, when she might have been taken to the German Hospital or to a workhouse infirmary, and that the police should in future call in the divisional surgeon of the force to see persons who have been rescued from drowning."

The Drainage of Colney-Hatch Asylum.

THE judgment of the Court of Chancery imposes on the Committee the duty of putting an end to the nuisance complained of by those who had property close by—that of the sewage of the Asylum being so disposed of as to injure and annoy their neighbours. This is satisfactory, as it clearly shows that not even a Public Board will be permitted, under a plea of discharging duties imposed upon it, to override the rights of others. On this question it is certain the law cannot be too rigorously upheld, and whatever the inconvenience or expense incurred by the Committee of the Asylum, we rejoice that they will not be suffered to make the neighbourhood of their excellent institution unwholesome or offensive. For once the law is found strong enough to put down a nuisance. It is a good lesson.

Refined Naphtha.

THE sad accident on the Brighton Railway has again directed public attention to the danger of conveying certain compounds in passenger trains, and it is to be hoped that some measures will be taken to lessen the fearful risks of travelling. The inquiry before the coroner has so far been important that it has placed before the public the truth as to some of these dangerous articles of commerce on no less authority than that of Dr. Letheby. From that learned Professor's evidence at the inquest we gather that some years ago "benzine," or "benzole," was a naphtha containing 90 per cent. of benzole.

"It was the most volatile and highly rectified spirit of coal tar, and was used for making coal-tar colours, being then thought to be the best description of naphtha for that purpose. But within the last few years it was found that a weaker naphtha, containing 40 per cent. of benzole, was better suited for the production of aniline reds; and they were now using naphthas containing as little as 20 per cent. of benzole. In English commerce all these were known by the name of 'refined naphtha of British manufacture,' but in France they called 90 per cent. 'benzole,' and all below, 'refined naphtha.' Every sample, however, contained a large proportion of benzole, which was the most important constituent with regard to the inflammability of naphtha. Benzole itself was 850, but Mr. Thacker said the spirit in question had a gravity of 875; still, it was very volatile at an ordinary temperature. Seven or eight drops dropped on a piece of paper, as he demonstrated, would dry up in a minute and-a-half; and in a minute and-a-half two drops of common naphtha would convert itself into a cubic inch of vapour at a common temperature, and diffusing itself through 37½ times its volume of air, would form an explosive mixture. Dr. Letheby showed this to be the fact by dropping some of the sample produced by Mr. Thacker into a glass bottle, and said if the proportion was 1 of vapour to 37½ of air, the temperature of the flame in an enclosed vessel—the flame which he produced—was 7,000 degrees Fahrenheit, and in an open vessel it would have been 5,000 degrees. The explosive vapour was many atmospheres over 20; therefore it evolved an inflammable vapour at common temperatures, which, mixed with air, was capable of generating heat enough to set fire to itself—not liable to spontaneous combustion, but when the vapour exploded the heat would be sufficient to set fire to the liquid or any combustible substance, with force enough to blow any vessel to pieces in which it was contained. He had read the evidence taken on the last occasion, and had no doubt at all that the refined naphtha in question had leaked, or had become diffused in the waggon, and the vapour mixing with atmospheric air, had formed an explosive mixture, which was fired by the light of the lamp held by one of the deceased men, and the explosion resulted, the burning naphtha being blown over them. He had also heard the evidence given by Mr. Thacker and by Mr. Kay, and was of opinion that the dangerous properties of naphtha were not sufficiently well known for the dangers which might arise from its carriage being guarded against, for the leakage of it into a confined truck might at any time, by the approach of a light, be the cause of a serious accident. Some regulations ought to be laid down for its carriage, and he thought there would be no difficulty in making a regulation which would not interfere with the commerce of the article at all. In reply to questions from several jurors, Dr. Letheby said he did not think naphtha could be ignited at a temperature below 1,500 or 2,000 degrees, and then it would require a flame to come in contact with it. A 'Davy' lamp would have prevented the explosion. The guard's lamp, being closed, was no protection, for whenever the air got in to feed the lamp the vapour would get in, but it would not get through the gauze wire of a 'Davy.' He suggested that as casks, although safer than carboys, would not prevent the escape of vapour, that trucks used for the carriage of such articles should be provided with louvre openings at the top for the purposes of ventilation; and that they should not be handed over from one company to another without the contents being made known."

It is satisfactory to learn that some of the precautions thus suggested were enforced by a distinct recommendation by the coroner's jury. An understanding was also given that the recommendation of the jury should receive "early consideration." We hope this phrase will not be allowed to cover further negligence, but that the Brighton Company will forthwith frame rules for their traffic in accordance with it, and that other companies will follow suit. If some such action is not taken by the companies, we hope the next accident will be succeeded by trials, and that the jury will in each case award "exemplary damages."

Royal Medical Benevolent Fund Society of Ireland.

A MEETING of the Central Committee of the above Society was held at the Royal College of Surgeons, on the 30th December. Present:—Mr. Tufnell (in the chair), Drs. Benson, Collis, Crocker, Fitzpatrick, Evory Kennedy, Law, Little, M'Clintock, Mollan, Quinan, Stewart, Albert Walsh, and Wharton. The death of Dr. Guinness having been announced, it was unanimously resolved:—"That this committee desires to record its deep regret at the death of Dr. B. Grattan Guinness, one of the honorary secretaries, by which sad event the society not only loses a warm friend, but is deprived of the services of a zealous and efficient officer."

The committee then proceeded to nominate a successor to Dr. Guinness, as an honorary secretary to the society. Dr. Marks, of 26 Hatch street, having been proposed and seconded, was elected unanimously.

The following letter from Dr. Robert M'Donnell to the treasurer of the society, Dr. James Little, was read:—

14 Lower Pembroke street, Nov. 30, 1868.

"DEAR SIR,—I beg leave to enclose you a cheque for £36 11s. 3d., a subscription to the Medical Benevolent Fund.

It is in fact (less income-tax) the pension assigned to me by Government as late medical superintendent of the Mountjoy Prison, and which I hope to hand to you annually as long as I continue to receive it. Circumstances into which it is unnecessary for me to enter, induce me to think that as I did not seek this pension on any selfish or personal grounds I can make no better public use of it than by devoting it to the service of the widows and orphans of my professional brethren.

"I made every possible exertion to obtain it, and through the unwearied exertions of Mr. Pimm, I succeeded. He fought the battle on public grounds; I, to vindicate my honour, as a professional gentleman. Having done so I am content, and only wish, for the sake of the excellent charity to which I give it, that it was a larger sum.

"I am, yours faithfully,
"ROBERT M'DONNELL.
"To the Treasurer of the Medical Benevolent Fund."

This letter having been read, the following resolution was passed unanimously:—"That the marked thanks of this committee be presented to Dr. Robert M'Donnell for his munificent subscription of £36 11s. 3d. a year, in accordance with his letter of the 30th Nov., 1868, to the funds of the Royal Medical Benevolent Fund Society; and that he be requested to allow his name to be recommended to the general meeting for election as a member of the central committee."

The treasurer further reported having received a letter from Mr. Courtnay, solicitor, enclosing a cheque to the credit of the society of £121 19s. 2d. under the will of the late Dr. William Kingsley, the founder of the society.

Outbreak of Choleraic Diarrhœa near Southampton.

A VERY severe outbreak of choleraic diarrhœa took place last week in the family of a farmer named Lashley, at Hambledon, near Southampton, which resulted in the death of one child, and the severe illness of every member of the family. His mother deposed that the deceased went to bed on the previous Tuesday evening in his usual health. He had for supper some soup, which they had procured from the soup kitchen, and nothing else. The next morning he seemed perfectly well. She had been ill from the previous morning with diarrhœa and sickness, and had not got up in consequence. Her husband and eldest boy had been ill from the same complaint; her other children had been ill also, and the one younger than the deceased was still ill, but better. She went down-stairs and found him and his younger sister both very ill; they were sick, had diarrhœa, and were very thirsty. She took them up-stairs and put them to bed They kept on asking for drink. Deceased grew worse, and attempted to get out of bed, and would have fallen through weakness if she had not held him up. They had had no arsenic, nor any other poison in the house, nor had they any reason to believe that any person had given any to their family.

Dr. Gaman said he did not see the deceased during his illness, but he had made a *post-mortem* examination of the body. From what he had heard of the symptoms he thought they might have been occasioned by arsenic, but he could find no traces of that or of any other irritant poison. He had tested the contents of the stomach of the deceased, and the vomit of the sister. In appearance they were both the same, except that in the stomach, which was a little darker. On opening the chest he found the left lung unhealthy and tuberculous, showing a disposition to consumptive disease. The right lung and the heart were healthy, and both sides of the heart were full of blood. The stomach was unusually flaccid, and the mucous lining here and there congested. He accounted for this from the vomiting; if it had been the effect of poison the congestion would have been more marked. The intestines appeared healthy, and were filled with fluid of the same colour as in the stomach. He attributed death to choleraic diarrhœa.

A verdict of "Death from choleraic diarrhœa" was returned by the jury.

Expenses at Netley.

In another part of our issue we make allusion to the personal expense to which the candidate is compelled to submit during his stay at Netley, and we think it right to corroborate our remarks on this subject by a succinct detail of his financial position at the end of a month's residence. His pay is, as our readers are doubtless aware, but five shillings a day. Let us see how far that will go towards keeping him like a gentleman and on an even footing with his fellows. The following are his monthly expenses:—

	£	s.	d.
30 Breakfasts, at 10d. each	1	5	0
30 Dinners, at 2s. 3d. each	3	7	6
30 Lunches, at 6d. each	0	15	0
30 Glasses of Ale, at 2½d. each	0	6	3
Washing	0	10	0
Contingencies	0	15	3
Library	0	2	0
Servant	0	10	0
Total, per mensem	£7	11	0

Each item is here set down at the lowest rate. All candidates must breakfast and dine at mess. Ale is not given, and one glass daily is charged separately and may be done without. The servant need not be paid under regulation, but only a single candidate was ever known who did not award this gratuity. The contingent expenses constitute the fund which keeps up the ante-room papers, &c., &c., and is compulsory under the regulations.

Set these charges against

	£	s.	d.
30 Days' Pay, at 5s.	7	10	0

and we have one shilling less than nothing for personal outlay. But in addition to these charges there are others payable during the first month of residence as follows:—

	£	s.	d.
Mess Subscription, 1st half	2	10	0
Library „	0	10	0
	£3	0	0

It thus appears that a candidate who eats, drinks, wears, or spends nothing outside the hospital *must* lose over £5 by his residence there. We need hardly say that, practically, the expenditure is at least double this sum; and thus a medical cadet is compelled to lose not only his six months of service, but to pay a certain sum, be it small or great, for permission to serve Her Majesty.

Medical Officers of St. Pancras.

Strange that there should always be something occurring to render the Guardians of St. Pancras notorious. It was but lately that an inquest was held on a woman who died very suddenly, and apparently from neglect. The jury prayed the Poor-law Board to interfere; and now, again, here is another fact. We quote from the *Parochial Critic*:—

"The stringency of the St. Pancras Guardians with their Medical Officers has deprived them of the services of Dr. Saul, who has worked both in and out of the house for a great many years. The poor speak highly of his kindness. One complaint out of the thousands of cases which have come under his treatment did not merit such a severity as that he should be harshly summoned to appear before the Board to receive a severe censure. Rather than submit to treatment which he considered he did not deserve, Dr. Saul sent in his resignation. The guardians may perhaps get in his place a more compliant officer, but will the poor on that account be any better cared for? The Chairman considered the letter tendering his resignation as most disrespectful. Is such great respect usual on such occasions? and did the writer receive it at the hands of the Board? It would seem that the present Board of Guardians are determined to get rid of all the old officers, good, bad, or indifferent. In the appointment of new officers they are not so particular, and the Poor-law Board has been obliged to restrain their excess of zeal in appointing officers to buildings, before the buildings were in existence."

Saving Life.

If the endeavour to save life is worthy of commendation, the great exertions of the Royal National Lifeboat Institution to rescue shipwrecked persons cannot be spoken of too highly. It has saved from drowning a total of 558 lives during the past year, besides rewarding the owners of fishing boats for saving 259 more. Since its formation 17,795 lives have been saved either by its direct efforts or its rewards for the exertions of others. These operations have, of course, involved a considerable outlay. In the past year it has spent £18,813 upon its lifeboat stations on the coasts of the United Kingdom.

Netley, its Pay and Expenses.

Now, when the Secretary-at-War has evinced the determination, at any risk or sacrifice, to reduce our military expenditure, would seem to be an appropriate time for calling attention to the probationary establishment at Netley, with a view to the inquiry as to what it does for the army medical officer in return for the six months of valuable time, and the not insignificant sum of money, which he leaves behind him at the Royal Victoria Hospital on joining his regiment. The theory of the probation at Netley is stated to be that after a candidate has established his proficiency in his strictly professional attainments, there are still certain special departments of his education of which it would not be reasonable to expect a knowledge from him, and which it would be impossible to leave to his previous teachers with any probability of his being fully conversant with them. In point of fact, it is declared that army surgery is a speciality to be studied under special circumstances, and with special opportunities not to be found but in a military hospital.

The scientific curriculum of Netley does not seem to afford good basis for this theory, and we venture to say that as far as medical, surgical, or scientific education is concerned, there is nothing in the course of study at Netley—if study it can be called—which might not reasonably be expected from the candidate, or which he might not learn with much greater advantage in three months after joining his regiment. In point of fact, the course of instruction at Netley is little else than a medico-military drill, in which the recruit is put through very elaborate manœuvering with very little gain to his surgical or scientific education. *Exempli gratia*—the orderly duty requires that the medical cadet should go at three o'clock, immediately after daily work is completed, and stay in the orderly-room until the next morning, an interval of about thirty hours, during which period he must saunter through the wards three times, and occupy the intervals in yawning, dozing, and filling up useless papers.

Now we do not by any means suggest that in the long run this medical drill may not be useful, still less that the educational duties of the various professors are not conscientiously or effectually discharged, but we *do* express our doubt that the information acquired in either department is worth the loss of six months without credit towards his service, and the expenditure of a smart sum by the medical cadet.

Netley Hospital is, we believe, really in intention and practice an institution for supervising the mess manners of medical recruits. They are, we suspect, sent to school for the second time, not for anything they are to learn there, but that their measure may be taken and recorded for future reference.

Is the nation content to pay as heavily as it does for the maintenance of a school of medical mess deportment, and are candidates for the Army Medical Service to waste half a year and be mulcted in a handsome sum for such an object?

The Viceregal Medical Appointments.

THE new Lord-Lieutenant has not yet made his selection of physician and surgeon-in-ordinary. The Liberal papers are urging that no one who voted against or refused to vote for the Government candidates shall be appointed to household offices. With such principles we have no concern, but we earnestly hope that the appointments will be conferred for professional eminence only. Her Majesty's physicians and surgeons, both at St. James's and her Courts at Edinburgh and Dublin, are chosen from practitioners who have attained the highest positions in their respective Colleges, and there is no reason why the similar offices about the Viceregal Court should be filled upon different principles.

Artists for the Palate.

THE authority of the *Produce Markets' Review*, a class journal of some note, informs us that gastronomy has taken its stand beside music, painting, and perfumery as one of the sciences of the senses. As we can have our pictures tinted to our taste, or our ears suited with the most agreeable strains, so we can for a few francs have our wines coloured and flavoured without incurring the expense of Chateau Margaux or Lafitte, any more than we must pay for Titian or Claude. According to a weekly Paris journal, *L'Eclipse*, there is now a class of artists who go round amongst the few dishonest growers and merchants wine-doctoring:—

"The public is aware that wines are adulterated, but it is ignorant, we think, to what an extent this is done, nor is it aware how curiously the wine industry is organised, and how each kind may be imitated by means of ingredients utterly innocent of any trace of the grape. We think, however, that nothing similar to the perfectly authentic document which we copy here, and which is printed and circulated in the trade, has yet been published:—

	F.	C.
For giving new wines the colour of old (per 230 litres) - - - - - - - -	1	50
For giving wines the taste and perfume of old Burgundy (per 230 litres) - - - -	3	0
For colouring in rose-colour and in red (per 230 litres) - - - - - - - -	4	50
For imitating with *vin-ordinaire*, Madeira, Marsala, Muscatel, Malaga, Alicante, Vermouth, Port, Lacryma Christi, Greenache, Sherry, Tokay (per 20 litres) - - - - - -	5	0
For imitating the taste of Beaune (per 230 litres)	3	0
For imitating Chablis (per 250 litres) - -	2	50
For giving white wines the taste of Champagne (per 230 litres) - - - - - - -	5	0
For giving corn-brandy the taste of Cognac (per 100 litres) - - - - - - -	6	0
For imitating the colour of Curaçao and Bitters (per 100 litres) - - - - - - -	2	0
For imitating Rum, Kirsch, and Absinthe with alcohol (per 50 litres) - - - - - -	6	0
For imparting to beetroot brandy the taste of *armagnacs* (per hectolitre) - - - - -	4	0

The above will show how easy and profitable is the trade in wines. We dedicate these facts at once to hard-drinkers, and to those who, careful for their health and for their purse, desire wine or some natural liquid in return for their money."

Hardwicke v. Diplock.

THIS dispute as to the validity of the late election of Coroner for West Middlesex, has, it would seem, only slumbered through the long vacation, and has woke up as bright as ever. The *quo warranto* is to be argued at the next sittings at Westminster; and if the law does not again consign the case to oblivion, the question will then be decided whether Dr. Diplock's "lambs" were entitled to vote as graveholders and watermen or not. Without imagining that Dr. Hardwicke is fighting the battle as the champion of the public, we are gratified that he is determined in the contest; for it is undoubtedly a very gross anomaly, and a very substantial grievance that the *bonâ fide* freeholders should be overridden by a multitude of made voters having no stake whatever in the district, nor any intelligence to guide them in the selection of the best man. It is thoroughly ridiculous that we still adhere to so unfair and unsatisfactory a mode of eliciting one of the most important of our legal functionaries.

Counter Practice in England, and its Value.

THE *Manchester Guardian* published recently a very amusing paper tourney between two druggists, which gives us some insight into the *arcana* of counter-practice, and the estimate in which it is held. A druggist, doing as he and hundreds of his fellows had done before, had undertaken the treatment of a wound in the neighbourhood of the shoulder, and was afterwards called as a witness to the injury. He was kept at the court for four days, and received 16s. as his pay, at which *multa gemens* he complained to the *Manchester Guardian*. He wanted to know whether "his *skilled* evidence" did not entitle him to a better fee; and another druggist replied that it served him right for going beyond his last.

As an expert we should say that the complaining druggist received about fifteen shillings, and we should consider the opinion of a surgeon on the commercial value of parafine oil worth about as much as the druggist's *skilled* evidence on wounds of the shoulder-joint.

Disinfection.

OUR recent remarks on this subject having produced several inquiries, we take occasion to state that the experiments of Professor Parkes are detailed in a Paper by the learned author, published in the recent Army Blue Book, a work to which we have already devoted considerable space.

We extract the general conclusions at which Professor Parkes has arrived :—

> "1. At temperatures ranging from 50° to 100° Faht. the carbolic acids and their preparations prevent the putrefaction of sewage to a great extent; measure for measure, they are all decidedly superior to the other substances noted. Double the quantity of sulphate of iron (viz., 120 grains to 4 oz. of sewage) had very little preservative effect at all, and the solution of the alkaline permanganate appeared almost as useless in the quantity added (two fluid ounces of Condy's fluid to four ounces of sewage), nor did the mixture of sulphate of iron and alkaline permanganate appear at all more powerful.
>
> "The zinc salts were also decidedly inferior, measure for measure, to the carbolic acids (crystallized and liquid), as the effluvia, though changed in character, were extremely offensive. The same thing may be said of the chloride of lime; when the smell of chlorine had gone off, it was clear that some kind of offensive change was going on.
>
> "I have no doubt, therefore, of the superiority of the carbolic acid series to all the other substance tried in the proportions given.
>
> "2. The amount of carbolic acid must, however, be larger than is usually stated. Of the commercial crystallized acids, at least 60 grains are necessary for the solid discharge of a man daily at a temperature of 50° Faht., and even then this amount does not prevent fæcal smell, and does not entirely arrest the development of rapidly moving vibriones. At a greater temperature (80° to 100° Faht.) the effect is less marked, and more of the acid must be used.
>
> "3. The liquid preparations of carbolic acid are more efficacious than the crystallized acids, and the impure preparations appeared more powerful than the pure. In the last series of experiments 60 grains of crystallized acid were much less powerful than one-half fluid ounce of Calvert's cheap carbolic acid liquid.
>
> "4. No decided difference could be traced between the carbolic of different makers. M'Dougall's crystallized acid in some experiments appeared slightly superior, in some slightly inferior to Calvert's, but the difference was not marked, and Bolton's liquid acid was as good as either.
>
> "5. The two disinfecting powders (Calvert's and M'Dougall's), though of such very different composition, appeared practically equal. Calvert's powder is carbolic acid, mixed with alumina and silicate of alumina; M'Dougall's is a mixture of carbolate and sulphite of lime and magnesia, and it makes the sewage to which it is added strongly alkaline; while Calvert's powder does not at the time affect the weak acid reaction of healthy sewage. Yet one powder for 17 or 18 days prevents putrefaction as well as the other."

Meetings of Societies.

We just announce to our readers that the Pathological, Obstetrical, and Clinical Societies will hold their annual meetings during the present week. At the meeting of the Pathological Society, Dr. Quain will be proposed to fill the chair, Mr. Simon, retiring from that office, an honour of which he is truly worthy, being one of its oldest and most devoted members. Three gentlemen will also be added to the vice-presidency, viz., Dr. Wilks, Mr. T. Holmes, and Mr. Simon. The Obstetrical Society will meet on the day of our publication, when Dr. Graily Hewitt is to be nominated as President, and Dr. J. C. Langmore, Dr. W. Leishman, of Glasgow, and Dr. E. J. Tilt, as vice-presidents, in addition to those already filling that office. The Clinical Society will hold its first annual meeting on Friday next. Mr. Paget will be proposed President on the retirement of Sir T. Watson.

Accounts from France inform us that cholera has made its appearance at St. Louis, on the west coast of Africa, and that the inhabitants are dying at the rate of 100 a day.

The Grove Hall Asylum, Bow, for lunatics, is increasing its charge for pauper patients.

The sanitary measures which have been adopted at Plymouth have, it is stated, rendered that town much more healthy.

From a report of one of the medical officers of the Derby Union we find that scarlatina is the most fatal complaint in the south district.

A midwife at Leeds was charged with having caused the death of a young woman by an attempted felonious operation.

In the parish of Rotherhithe the Embleton and Horncastle's Charity gave 2s. each to 51 females, the oldest 97 and the youngest 68 years old. The medical officer of Health says the parish is one of the healthiest in England.

It is very probable that Dr. Brown-Séquard will ere long occupy a chair in the Paris School of Medicine, a position which the entire profession will feel very great pleasure indeed to see the illustrious pathologist adorn.

At the Royal Institution on Thursday next, at 3 p.m., Mr. Rupert Jones will lecture on "Protozoa;" Friday at 8, Professor Tyndall on "Chemical Rays and Molecules;" Saturday at 3, Professor Odling on "Hydrogen and its Analogues."

A meeting has been lately held at Stamford, presided over by Lord Exeter. There was a numerous attendance, including medical men. A resolution was passed unanimously "that it is desirable to take steps to adopt a more effective system of drainage, with a view to improve the sanitary condition of the town."

Dr. Letheby, medical officer for the City, has just presented to the Commissioners of Sewers his report on the sanitary inspection of shipping within the district of the City of London during the last two years, in accordance with the provisions of the Sanitary Act of 1866. We can only mention it now, and purpose a more detailed notice in a subsequent number.

Vaccination was introduced into Russia one hundred years ago by the Empress Catherine II., and the anniversary of that event is to be celebrated in a few days at St. Petersburg. The Government has offered a prize of 3,000 roubles (£400) for the best history of vaccination. The competition is open to all Europe, and the history may be written in any modern European language.

SCOTLAND.

EDINBURGH.

The questions relating to the Edinburgh Infirmary Site, and the Water Supply, are still *sub judice*. Difference of opinion prevails, as might be expected, on both these subjects, which appears day after day in the correspondence admitted into the Scotch newspapers. The amount of money which may be required in carrying out the separate proposals, enters largely into the discussion, though other and more important considerations have their acknowledged weight. The last action taken was on the Water Supply, at a meeting of the Town Council on 29th December last, when they decided to delay consideration of the bill till the Special Committee complete their investigation into the new scheme of the Water Company, and report to the Council.

DECREASE OF JUVENILE CRIME IN EDINBURGH.

On Saturday, the 26th ult., a meeting was held in the Original Ragged Industrial Schools in aid of the emigration fund of the institution, the Earl of Southesk in the chair. Dr. Guthrie stated the object of the meeting. He also read a return of the number of juveniles committed to the prison of Edinburgh in the twenty-two years ended 30th of November, 1868, as showing the large decrease that had occurred since the institution of the various ragged and industrial schools in the town. In 1847 the number of juveniles committed to prison under 14 years of age was 260, while in 1868 it was only 52. The number of juveniles under 17 years of age committed in 1848 was 552, while in 1868 there were only 76.

EDINBURGH INDUSTRIAL BRIGADE.

The friends and supporters of this Institution held their first annual meeting on the 30th December, in the Craigie Buildings, St. Andrew square. The chair was taken by Admiral Ramsay, C.B. The report stated that when operations were commenced, twelve months ago, as a mere expedient to provide the boys with work, as a means of paying for their food and lodging, they were engaged as shoeblacks; but this from the first was intended to be merely temporary. As a boy evinced the desire to improve, a suitable situation at some regular employment was provided for him; and it was with much gratification that the directors reported that the whole of the boys, with the exception of two, were now not engaged in shoeblacking, but in regular employments—as message boys, apprentice painters, bakers, joiners, grocers, coopers, slaters, japanners, &c.—earning from 2s. 6d. to 8s. a-week; and the thirty boys at present accommodated in the institution earned together £5 8s. 6d. a-week, while other boys, who had been in the brigade and who were not in connection with it, had also employment, and were earning from 4s. 6d. to 7s. each. The number of boys who had been assisted was 136, for periods varying from two days to the whole time the brigade had been in existence. The total earnings of the boys amounted to £189 13s. 10d., which was sufficient to pay the cost of the food and the rent of the premises. The report was unanimously adopted. Medals and prizes were awarded to a number of the boys for good conduct.

GLASGOW.

The first annual meeting of the Medical Missionary Society has just been holden. Dr. Andrew Anderson took the chair. The funds are in a prosperous condition. A dispensary has been established for the gratuitous supply of advice and medicine, under the direction of a medical superintendent.

COATBRIDGE TOWN AND DISTRICT.

Fever of a severe type has again broken out in this neighbourhood. At Holytown sanitary arrangements are being made, to prevent, if possible, the spread of the disease; but the condition of the above villages is very bad, the drainage is everywhere defective, and there is no water system whatever. Considerable uneasiness consequently prevails, and many persons urge the necessity of the Parochial Boards of the parishes of Old Monkland and Bothwell, as the local authorities, to take active steps to remedy the evils. In the villages of Calderbank and Chapelhall, Dr. Robert Young was the principal medical attendant, and for a time he was assiduous and indefatigable in his exertions to save the sufferers, but we regret to announce that he was seized with the epidemic, and the grave was closed over his mortal remains, with military honours. At an early age Dr. Young has fallen a victim to his profession. He was a young man of great promise, and, having a wide practice, his loss is greatly felt by a large community. The deceased gentleman was a lieutenant in the 100th L.R.V., unmarried, and a native of Dunfermline.

We noticed in our last issue that a petition againt the election of Mr. Moncrieff for the Universities of Glasgow and Aberdeen had been presented. We have subsequently been informed that it will be abandoned.

During the last year 346 women were admitted as in-door patients to the Glasgow Maternity Hospital, and 601 were attended at home. Females are being instructed to act as midwives and ladies' nurses.

GERMANY.

(From our own Correspondent.)

Vienna, December, 1868.

Entrusted with the task of preparing the correspondence from this capital for the Medical Press and Circular, I shall endeavour to make my letters interesting to the readers of that excellent journal, by giving from time to time information, not only upon such new contributions to medical science as may be made, but such social gossip and professional news as I think my English brethren will find acceptable. No doubt they will be surprised at what is regularly seen in Vienna. I must request the reader to regard my letters as the reflection of medical life in Austria; and you, my dear Editor, to use freely your right to excise what you think unfit for your journal, and to rectify for me the mistakes in your language into which I fall.

Suppose I begin by a notice of some of our chief medical institutions, schools, and professors.

We have at Vienna—1st, a large general hospital; 2nd, the hospital at the Faubourg Wieden; 3rd, the hospital for Israelites; 4th, that for convicts; 5th, the hospital of the Brothers of Charity; 6th, two hospitals of the Sisters of Charity, at the Leopoldstadt and Gumpendorf; 8th, Rudolph's hospital; and 9th, the hospital at Sechshaus.

Some description of these hospitals shall follow on a future occasion.

There are two cliniques for practical pathology and therapeutics, conducted by Professor Skoda and Professor Oppolzer, both born in Bohemia. Professor Skoda is with Professor Rokitansky the founder of the celebrated modern physiological school of medicine, based on pathological anatomy; author of an excellent work on Auscultation and Percussion—the Vienna oracle for diseases of the chest. He represents the negative school of medicine, whilst Oppolzer represents its positivism. Skoda is the leader of the nihilists—sceptics; places the accent of medicine more on diagnosis and prognosis than on therapeutics. His system is dry and short as his character, and he speaks scarcely a word in a private consultation. He represents pure science abstracted from life. He is a member of the Academy of Exact Sciences. He recognises only a few remedies as valuable: *these are* (except sodæ bicarb. which you will find in most of his prescriptions) *all specifics*—cannabis indica, morphia, mercury, quinia (this almost in all chronic diseases), lead, iodine, argenti nitr., digitalis. He very seldom recommends mineral waters. His speciality is the diagnosis of diseases of the organs of the chest. He and his school expect the true therapy from the progress of organic chemistry. He was consulted by the young Empress of Austria in her dangerous illness of the chest, and sent her Majesty first to Madeira, then to Corfu, and finally to Venice.

Professor Oppolzer (Hofrath, Councillor of the Court of Saxony) was formerly professor at Leipzig, and is now one of the most renowned physicians at Vienna and in the whole of Austria. He is as much celebrated in diagnosis as in therapeutics—neither nihilist nor physician of the old fashion—but prescribes all kinds of remedies (mostly specifics, and in small doses), and all kinds of mineral waters. He pays much attention to the chemical and microscopical analysis of urine, which is made at every interesting case under his care before the students. He is the very ideal of a true teacher-professor. He has a passion for teaching his pupils, not only diagnosis, but the *savoire faire* in practical life. He combines science with life. An invalid on his clinique is better treated than any of his patients in the private practice, where he is sometimes superficial for want of time.

A curious circumstance I may remark here. Considering that every professor of therapeutics has the duty to warn his auditors from error—from false paths to the truth—it is strange, and you may be surprised to hear, that neither the one nor the other of these professors, nor any of the medical authorities of the town, ever says a word about homœopathy (for or against); but, nevertheless, they meet homœopaths in consultation, not as to treatment, but only diagnosis. This can be from no selfish motive, for these professors are notably honest and very rich men.

Professor Rokitansky, founder of pathological anatomy, is the sun that brought light in all the branches of medicine, and penetrated them with his profound exactitude. He is the very leader and founder of the Viennese physiological school, and was named for his merits, not only member of the Academy of Sciences, but also Councillor of the Court, and President of the Commission for the Reformation of the University. And when freedom and the Constitution entered Austria he was called by the Emperor to the House of Lords, or Senators (Upper House), where he excited public attention by his excellent speech against the Concordat, as destructive of the arts and sciences, as well as incompatible with liberty. The abolition of the principal part of the Concordat and liberty of worship is partly due to this man, who is as great a politician, statesman, patriot, as professor of medicine and orator.

Oppolzer was begged by the Emperor Nicholas to go to see the Duke of Paskewitch—a doubtful case of ulcus rotundum ventri—in the middle of winter, and for precaution against catching cold he sent to him a magnificent fur.

When the Imperial Prince of Russia was dying at Nice, the Emperor Alexander begged him to accompany him to the bed of his son; and although they arrived the day before his death, which could no more be prevented, Oppolzer was the only physician (amongst the many French and Russian present) who dictated the true diagnosis (exostosis of the interior of the skull, caries of the os sacrum, psoitis), which was entirely confirmed by the autopsy.

He is so celebrated that no invalid foreigner of distinction, no patient from the provinces, or from Russia, Wallachia, Moldavia, or Turkey, comes to or passes through Vienna without consulting him. No one of distinction, few rich ones, are allowed to die without having consulted him beforehand. He almost never undertakes alone the treatment of an invalid at Vienna, he goes only in consultation. His son is a famous astronomer. It was he who observed the last total eclipse of the sun at Aden, supported by the generosity of the English consul there.

Oppolzer's reputation began at Prague, when he was still assistant of Professor Krombholz, by this singular case:—

He was consulted by an old general, who tried all remedies (external and internal) against a continual convulsion (clonic cramps) of the right hand. Oppolzer examined very carefully the hand, and asked him to show his stick, which had a silver knob. After having remarked a grey circle in the palm of the hand, he declared that the knob of the stick was not genuine silver, but falsified with lead. The general would not allow that he carried anything false. But chemical analysis proved the fact. The two different metals (electrically opposed) formed with the sour sweat of the hand a voltaic pillar; and thus the convulsions can easily be explained. Oppolzer ordered that the silver knob be put away, or the stick changed, and this being done the convulsions ceased very soon, without any other remedy. Oppolzer has a very modest appearance, and does not care for his toilette. His hand is as delicate as a lady's.

P.S.—Just as I am going to send this, I hear with sorrow that Professor Skoda is very dangerously ill. When I saw him a few weeks since, he looked an invalid, or as if some great change had passed over him, and leaving him, I remarked to an English friend, "'There's something rotten in the state of' our great Skoda." So I fear that his sickness will be fatal.

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. VI.

The point was settled, my relative being a gentleman of the good old school, one of the class that try and force us to a focus, hold us to it with the tenacity of a *nisi prius* pleader, and clinch a point with detonating decisiveness. There was no nonsense about *him*. I decided in favour of London, and he *meant* it thenceforth; consequently, within forty-eight hours from the time of my decision I was in the full swing of preparation for a professional dêbut, determined on my arrival in the vast metropolis to seek and to find, first, an appointment, and subsequently a groove, wherein I might settle down, and whence I should radiate a terrestrial medical meteor, a metaphysical phenomenon.

Whether I journeyed by river or by road, to the reader of these Pencillings it matters not one whit to know. Suffice it that I arrived in London according to programme, and in due time called on a medical friend or two—old class fellows—and explained to them the object of my trip, my prospects, and my final intention. My medical friends advised me to seek an appointment by means of the usual channels—the Press and medical agents—promised to be on the *qui vive* in my interest; gave me some sound advice founded on some years of experience; proffered to me the hospitality their positions enabled them to offer; and finally requested of me to "look them up occasionally" so as to apprise them of any chance of success, and the probability of attaining the *first* object of my very laudable ambition.

London was not new to me; I had previously made to it flying visits, during which I naturally took opportunities to see theatres, picture galleries, museums, the Parliament houses, St. Paul's, Westminster Abbey, and many other places historically famous, or made—by means of the current literature of the day notoriously—so; consequently, as my object in London on this occasion, was likely to influence in a great measure my future prospects, the wonders of the mighty metropolis—if not completely lost to my faculty of observation—made very little impression on me as I passed them, for the accomplishment of the task on which I had set a full, a bounding, and a highly sensitive heart, solely occupied my thoughts, and entirely influenced and stimulated my movements.

Undoubtedly the first brush during the ever raging battle of medical life is generally a very severe and a very trying one indeed, more especially, if during the encounter "ammunition" run short, and there be no likelihood of receiving "shot" from a friendly locker—a state of things no way uncommon amongst the newly-fledged medical element all the world over—and if the medical soldier of fortune, escapes with a scratch or two, and does not heartlessly and dispiritedly retreat from the encounter—but bravely storms and captures the *first* citadel, he has every reason to thank his stars, to feel grateful to his good angel, and to beg of his relations *not* to remit him any money "just at present."

Now it so happened that my last visit to London was made during the time designated the "dull season,"— when a considerable section of the "upper ten," and a very large section of the under cut of society too, goes to the sea-side, or somewhere else.—The "Houses were up," and London life had just commenced to be flat, stale, and unprofitable, a state of things that "told" so effectually on my brilliant prospects as to enable me for many weeks to perambulate the streets in a hopeless, blissless state of idleness, ere the smallest chink through which I could favourably behold a ray of sunshine presented itself to me. True it is, however, that the "usual channels" brought me into communication with medical gentlemen actually in want of, or about to require assistants, yet negociations seemed fruitless just at that time. It was in fact the dead season, and *rigor mortis* to my mind, seemed to influence everything medical.

I was beginning to despond, I do not deny this—six weeks "tramping" the London streets, seeking and finding nought save the cold shoulder of disappointment daily during that time, was more than enough to damp the ardour, and to cool the courage of a temperament far less sensitive, and of a body physically superior to mine—notwithstanding the kind and cheering notes from home, and from my relatives and the monetary considerations of which they not unfrequently were the custodians.

At length a "golden opportunity" presented itself for my acceptance, at all events I thought so. It was caused by a "death vacancy in a respectable district of London." It offered many advantages for little money, and the gentleman in whose hands the vendor placed it for disposal, was a medical agent who had taken some pains to procure me employment, and now strongly advised me to seize on this Eldorado. I did so, and from my small experience in such matters—together with the state of despondency into which I was drifting on account of my long spell of idleness, considered the opportunity so golden as to be embraced out of hand, lest an interloper might put in an appearance and snatch the prize. Therefore I wrote to my relative, stated to him that no appointment appeared likely to offer for my acceptance, and at the same time enclosed him the opinion of the agent as to the value of this golden opportunity. In due time my relative agreed to my proposal, "provided I were really confident of success," and also provided that the sum offered by *him* would be received by the vendors as equivalent to their legal rights in the "vacancy." After considerable negociation I became the purchaser; my relative stood by his promise, the vendors received payment, I took possession of the premises, and a deed of assignment at the same time, and within a very short period my name and title "on a burnished field of brass," faced one of the panels of "death vacancy's" entrance door, to note Time's changes, the uncertainty of our whimsical world, and to "astonish the Browns."

Quid Nunc.

◆

LONDON ASSOCIATION FOR THE PREVENTION OF PAUPERISM AND CRIME.

The formation of this Society is one of the signs of the times, and the information it is likely to accumulate and diffuse must inevitably tend to the welfare of the community. The object of its promoters is definite, and we would draw attention to the word *prevention* as the most important in the title of the Association. Other societies have occupied much attention by discussing questions relative to how we should deal with criminals and paupers. If we are correctly informed, this new Society does not intend to claim ground already occupied, but believes that there is plenty to absorb its energy in the one point—prevention.

Few can be careless on such questions. A certain kind of indifference may arise from a conviction that prevention is altogether impossible—that the greatest efforts are likely to produce no result. Still, even they will respect the opinions and the action of those who think otherwise, and it is probable that a languid interest may be stimulated into active co-operation by the labours of the Society. In this manner very great good may result.

The medical profession is deeply interested as a class in all the questions relating hereto, and its journals will therefore gladly aid the cause. The Association may be said to have originated in a paper read in June, 1868, by the Rev. H. Solly. A committee was then appointed to pursue inquiry. That committee has developed itself into the Association, the first formal meeting of which took place last month in a room lent by the Society of Arts, and was presided over by the Earl of Shaftesbury. The paper of the evening was by Dr. Hawkesley, and treated of the pauperism and the charities of London. That paper gave rise to much of the recent discussions that have appeared, and we now give an abstract of it:—

Dr. Hawksley having premised that to him had fallen the task of investigating the means of opposing pauperism, proceeded to give the following as the chief facts elicited by the inquiries of himself and the committee:—There are in London 606 charities which give their annual income, and 382 which do not. The income of the first number is £3,857,119. To allow for those whose sphere of operation was out of London, or only partially in it, £144,655 was subtracted, leaving £2,712,464. Estimating the income of the charities which do not give returns at the same ratio, £1,499,176 was added, and that made a total of £4,211,630. Classifying the charities, it was found that £121,414 was spent in treating mental or corporeal disease, £951,302 in supplying the ordinary necessaries of life, and £426,460 for educational, training, moral, and religious purposes. So far Fry's "London Charities" was used as a catalogue, by no means complete. In 1861 Mr. Sampson Low estimated the income of 640 institutions at £2,441,967, stating the ratio of increase in the preceding ten years, and if that ratio had been maintained the income might be set down now at £3,011,753, which showed that the present calculation was supported by that of seven years ago. There could, then, be little doubt that four millions was collected and distributed annually by the charities of London, while another million might be set down for offertory collections, &c., and an additional quarter of a million for private almsgiving. The police magistrates distributed about £9,600 per annum. The parochial expenditure in 1867 equalled another million and a quarter, exclusive of the common fund expenditure for infirmaries, &c. State expenditure in London for education might be set down at £100,000, and for the repression and punishment of the crime which might fairly be put down to want of moral and industrial training at £80,000. The result was that at least £7,000,000 was spent annually in London in dealing with the requirements of poverty. If one-eighth of the whole population, or 400,000 persons, were dependent on the other seven-eighths, the sum named would supply to each £17 a head for every man, woman, and child, or to every family of five persons £85 per annum, with £50,000 to spare for the expenses of collection and distribution. During the last ten years the population of London had increased one-sixth; the pauper part of it had increased one-half. Of offenders and suspected persons known to the police and at large in London there were, in 1867, 8,964; and in 1868, 10,342. The discontinuance of transportation turned 2,000 convicts loose upon the community every year, in addition to 100,000 of all sorts from our gaols. In London there were 100,000 children destitute of proper guardianship, and exposed for the most part to the training of beggars and thieves. He doubted whether a parallel to this picture could be found out of the kingdom of Dahomey. He attributed this condition of things to erroneous method and want of organisation. The new Poor-law dealt with destitution only in its completed state, and did not attempt to prevent pauperism. Through it we attempted to discharge the duties of humanity by proxy; we multiplied workhouses and officials, prisons and police, and how much did we do to prevent pauperism and crime? Including training and industrial schools, he had made out a list of thirty preventive institutions with an income of £60,000 per annum. The second error of method (indirectly connected with this subject) was the diminution of our food supply by the pollution of our rivers. Experience had shown that we had an army of professional beggars, and that the aid afforded by our institutions often failed to reach those most in need of it.

Dr. Hawksley next noticed the causes which prevent the charitable institutions from checking the growth of pauperism, and stated his views as to the action required. He proposed—First, a modification of our Poor-law system. There should be a more discriminating treatment of adults, and sufficient support given to the aged and infirm in their own homes, as well as to the sick (allowing for obviously exceptional cases). The ablebodied, in health to work, should be set on labour that would pay for maintenance. All children found without proper guardianship ought to be apprehended and sent to industrial schools, the parents being made, if possible, to contribute to their support. The schools should be made as far as possible self-supporting by apprenticing the children in sufficient time to make their labour profitable, or by employing them partially in factories. The difficulties in the way of the successful administration of the charities of London he proposed to remove in this way:—1. By the union of all the charities, including the parochial, in a common understanding and obligation to attend only to applications authorised by an office of registration and inquiry placed in every parish or district. 2. Each office to be in communication with the others, and all to be subject to a central one, which latter would act as an office, not only of general control, but also for the general audit of charity accounts and for inspection of the annual reports of the same. The district office, on the other hand, would be constantly open to the application of all distressed or sick poor; the officer in charge would enter the particulars of the applicant and his requirements in such a way as would identify the individual, and be evidence of truth or falsity of statement; he would then, or subsequently, either personally or by the agency of a district visitor, go and verify the statement, and he would at the time of application, if necessary, supply to the applicant a card directing him or her to the most appropriate charity or institution for the requisite relief, the card so given being the necessary but all-sufficient requirement by the charity or institution to which it was directed. In some instances it would be possible, when the inspector found that the applicant was not altogether destitute, to write on the card,—"The bearer can pay something towards the expenses of the charity;" and this would be as useful to the applicant as the institution, for everything that favours independence tends to diminish the mean and unmanly spirit of unnecessary dependency. Such a machinery of a central and of district offices would constitute, in effect, a "police of charity." It would require for its effectual working a large staff of voluntary or unpaid district visitors, who would be selected for their fitness, and act under the direction and government of systematic rules of conduct and management. The district officer would teach them their duties and be responsible for their conduct, keeping a record, to be carefully and daily filled up, in which the particulars of every applicant would be "ledgered up," and which would serve as a book of reference by other officers or by the public at all times, so that, when any one applied to private persons for relief, the latter could directly ascertain what had already been done in his or her behalf. If it were objected that such a system of charity police would be very expensive, it was easy to suggest how that would be met. Let charities pay £1 per cent. of their annual income to a common fund for this purpose, and on only £4,000,000 of their income £40,000 per annum would be immediately produced. There are thirty-six unions in the metropolitan area—suppose an average of five district offices to each union, and the expenses of each office equalled £200 a year, the cost of the 180 offices would thus be £36,000 per annum, leaving £4,000 per annum for the central office. It might be found that fewer offices would do, but if not the work performed by them would be of the highest public utility. We should then obtain a public and independent audit of all charitable accounts and reports, which would strengthen the position of the good and deserving charities, and either reform or annihilate the bad ones. This agency would supply the poor with an easy, sure, and expeditious method of obtaining succour for the destitute and the real sufferer, for the office would possess the power of opening the door at once to the most suitable help at all hours of the day or night. Next, we should be able to prevent entirely the trade of begging, by identifying every dependent person, and obliging him to keep to his own district for relief, the correspondence of the offices making it impossible for the same person to obtain a ticket of relief from two offices, aided as the offices would be by the weekly reports of the different charities, and also by the reports of the district visitors. Put this system in complete action, and the law might mercifully sweep every beggar from the streets. The machinery thus sketched out would subserve other useful purposes. Each of these district offices might constitute a centre of parochial usefulness to which Mr. Solly's notions of working men's clubs might be affiliated, or in other cases the head-quarters might be allied to them of those organisations of frank-pledge, of registration, and of friendly supervision which were devised to favour the honourable industry of the reformed criminal.

Correspondence.

DR. BARTON ON SYPHILIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Having entrusted me with the review of Dr. Barton's book on syphilis, and endeavoured impartially to carry out your intention, allow me to answer some of the author's remarks in the number for Dec. 16, on what might appear uncandid representations or mis-quotations from his book. Though Dr. Barton hints that those "who are ignorant of the subject" are liable "to confound the question of the plurality of venereal poisons and of the plurality of the syphilitic poison," he will, I hope, give me the credit of having discerned the difference, as I mentioned his following the usual trifold division; and on the question he chides me for, I speak of "this sore" as specially alluding to true syphilis. It is with regard to "this sore" that it appeared to me the author is "rather inclined" to revive the theory of the plurality of poisons. He quotes Diday—"That the primitive lesion offers in its form the reflection of all those influences which at the moment when we see it contributes to make the syphilis in the particular patient who has it, either severe or mild." Dr. Barton adds his own idea that when a chancre has a deep ulcer with a sloughing surface or high indurated edge it is a severe case; but if there be simply an indurated nodule without any, or scarcely any, ulceration, that is not a bad case." Again, p. 100:—"Should phagedenic ulceration attack an indurated chancre, the prognosis of future symptoms will be highly unfavourable." These remarks would, I think, tend to impress his readers that he is rather inclined to recognise—

The sore or ulceration that will be "a severe case."

The sore or ulceration that will be "not a bad case."

The ulceration where "the prognosis of future symptoms will be highly unfavourable."

As the author does not seem to me to characterise the "severe case"—the "not a bad case"—and that where "the prognosis of future symptoms will be highly unfavourable," as being due to a peculiar constitution, or point out what that constitution is, it is but reasonable, I think, to assume they are modified poisons; at all events, as he does not mention whether "a severe case" or "not a bad case" is due to the proportionate development of the same symptoms, or to the development of special symptoms for each, we rather conclude the latter to be most likely.

As to the subject of nervous affections, I must still say that I think, considering their interest, they might have been more largely dwelt on. The readers of the book can judge.

As to mis-quotations Dr. Barton twits me with, the word "their" is, by a typographical error obviously, put "other."

No object could have been gained by so misrepresenting the quotation.

As to the word *guide*, though Dr. Barton says "not employed by him at all," I find in the first few lines of the Preface the author stating, that "a book on syphilis was much needed," and that "this conviction had arisen as those interested could not find the *guide* they wanted amongst the books accessible to them." Again, p. 67, he states:—"The interest with which these lectures (referring to his own) were always listened to, has encouraged me to make an attempt to supply the want which was felt for a written *guide*." If this does not shew that the intention of the author was to supply a "written guide," I can see no other explanation of the expression.

I trust I gave a sincere and truthful impression of the merits of the book, which I consider a "credit to the Dublin School" and to the author.

I am, Sir,
Yours, &c.,
THE REVIEWER.

A WORD FOR THE VESTRY OF ST. PANCRAS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It appears to me that a false issue has been deliberately raised in the discussions as to the late appointment of a medical Officer of Health. It is all nonsense to talk about the higher branches of the profession confining themselves to one diploma, and the general practitioners taking two or more. It is worse than nonsense—it is untrue. The consulting surgeon and physician who simply puts F.R.C.S. or M.D. after his name, in ninety-nine cases out of a hundred has the right to put several other initials. Practically he only puts one, that of his highest qualification, just as a duke may have half a-dozen inferior titles but only uses one.

When the one degree plan shall be adopted, it will be time to say one diploma shall be enough for a public appointment. While the present wretched system, or rather want of system, lasts, I think in every case the double diploma should be insisted on.

Besides, all this cloud of dust has been raised for what? clearly in the interest of one ineligible candidate, who, whatever his merits, is, I am told, actually after all a general practitioner, with one diploma. I admit he has given much attention to sanitary subjects, and would probably make a very efficient health officer, but it is invidious and unjust to assert that the vestry has chosen a less capable candidate. Dr. Stevenson, as a Professor at Guy's, who has made his mark, who has proved his knowledge by gaining *several* of the very highest diplomas, and whose position has been acknowledged by the University of London, which appointed him an Examiner, had claims with which few could compete, and the press friends of the disappointed candidate would have done wiser to confine their vexation within reasonable limits, and not provoke inquiry into this miscalled job, which, after all, gave the appointment to perhaps the best man.

I am, &c.,
EX-OFFICER OF HEALTH.

Obituary.

DR. THOMAS PUREFOY, OF LUCAN.

WE had hoped that we had closed our Obituary Notices for the year 1868, but alas! no; we have to record the death of Dr. Thomas Purefoy, of Lucan—an old friend and the contributor of many interesting and valuable papers, not only on midwifery, which may be said to have been his *specialité*, but also on subjects connected with medicine and surgery.

Dr. Purefoy has been for many years Medical Officer to the Lucan and Leixlip Dispensaries. Previous to his obtaining that appointment he was Physician to the Cloughjordan Dispensary and Fever Hospital, so that during almost the whole of his professional career, extending as it did over a period of thirty-six years, he has been connected with Poor-law appointments. He succumbed at last, however, to phthisis, contracted during exposure to the hardships of dispensary practice. Had he retired from these duties some months ago, and gone to live in a warmer climate, as his medical advisers recommended, he might still live to ornament the ranks of our profession; but the fact that as yet there is no retiring pension given to Poor-law Medical Officers who have devoted their energies during the best years of their lives to the service, may perhaps have decided him to remain at his post and die in harness. We hope that this state of things will not long continue. Meanwhile it is our painful duty to record that a kind friend, an accomplished physician, and a Christian gentleman has departed from amongst us.

EVERARD AUGUSTUS BRAND.

THIS gentleman died lately at the advanced age of ninety-three. He entered St. George's Hospital in 1795, and was connected with it for several years as Visiting Apothecary. He succeeded to his father's practice at the West End, and was successively Examiner, Warder, and Master of the Apothecaries' Company. He was held in great respect by all who knew him.

◆

NOTICES TO CORRESPONDENTS.

TO CORRESPONDENTS.—We would impress upon our numerous correspondents the necessity of making their lectures, Original Communications, or letters intended for insertion as short as is consistent with the subject on which they treat. We find it necessary to intimate this to our many friends, in consequence of complaints continually reaching us from contributors, who are anxious to obtain an early publication for their papers.

IN deference to the wishes of a large number of our readers, we intend forthwith to devote several columns weekly to *excerpta* from the best British and Foreign journals, in order to keep our subscribers *au courant* with the progress of medicine and surgery in all parts of the world. As our correspondent also suggests, "It will then be a very readable and practical paper; variety is pleasing."

DR. JACOB'S Lecture on the Eye, with illustrations in six colours, will appear in our next

MR. DENNIS PHELAN.—It *is* our intention to publish your letter on "Lying-in Hospitals," as soon as our space permits. It would have appeared 'ere this, but for two reasons: First, on account of the unusual number of communications in hand, and the length which proceedings of societies and lectures have occupied; and secondly, because of the great length of your letter, which occupies twelve closely written fscap. folios, which will, when in type, fill at least three columns of correspondence. Our apologies must therefore be made on these grounds.

DR. E.—Your communication has been received, but we do not feel justified in opening our columns to quarrels between members of the profession, which are merely the result of personal animosity. No good can possibly accrue by the publication of such matters, and the less said about them the better.

THE index for the last volume of this journal will appear in our next.

DR. LEARED.—Your proof, which was not received until ten o'clock on Tuesday morning, was too late for one portion to be corrected.

DR. J. LAMPREY (Portsmouth), will receive a private note.

Introductory Lecture

TO THE

COURSE ON HUMAN ANATOMY

AT THE

LONDON HOSPITAL MEDICAL COLLEGE,

By Walter Rivington, M.S. Lond., F.R.C.S. Eng., &c.

Delivered Oct. 5, 1868.

Gentlemen,—The welcome which it is my privilege and pleasure to give you to-day at the commencement of my course is given under a full sense of the increased responsibility which has been laid upon me, nor can this sense of responsibility be in any degree diminished by the kindness and consideration which I have ever been accustomed to receive from my classes in this college. You are aware that during the last two years I have been associated with Mr. Adams, the senior surgeon to the hospital, in the delivery of the Anatomical Lectures, and that that association has now come to an end through Mr. Adams's resignation. Under any circumstances, the retirement of a popular lecturer, and a favourite teacher, must be a matter of regret, but how much must a regret of this kind be augmented by the fact that this retirement was occasioned by the failure of health last winter—health now happily restored—and that it is a retirement from an office which has been held for no less than thirty-seven years. On a former occasion I took the opportunity to allude to the several qualities which contributed to form Mr. Adams's excellence as a teacher of Anatomy, and which I feared were "conspicuous by their absence" from his colleague. There was the conciseness of description, the presentation to the class of the main facts of the subject in hand, with the avoidance of details that would weary the attention, and not be retained in the memory; there was the interesting anecdote, there was the illustration of Anatomy in the light of a matured surgical experience, and, to relieve the whole, there was a quaint pervading humour which gave animation and interest to the terse and pithy delineation. But there were two other qualities which caused Mr. Adams's success as a lecturer. These were his punctuality and his sympathy with his audience. Few men have surpassed Mr. Adams in regularity and punctuality as a lecturer. In former years no record was kept of attendance in the lecture room. Now, the same register marks, and marks most properly, the attendance of both teacher and student. It is well that you should know this fact—for if any pupil is inclined to complain of hardship because his name is taken at lecture—let him consider that it is a correct moral procedure intended to ensure a fair attendance in exchange for signatures—and let him remember that the attendance of his teacher also is checked. Had there been any record kept of Mr. Adams's attendance during the thirty-seven years of his lectureship, I imagine that the number of times he had been "unavoidably prevented from lecturing to-day" would have been found to be exceedingly small, while still smaller would have been the occasions on which he was behind his time. Another and most able lecturer, a lecturer on medicine at this college, Dr. Parker, was also a remarkably punctual man. He lectured here for ten years, and I believe I am right in affirming that during that period he only missed one lecture, and *that* owing to his having been taken ill in the lecturer's room just before the time for commencing it. The celebrated Abernethy was very particular in this matter. It is related of him that he refused to miss his lecture even on the day his daughter was married, but in festive array he went down as usual to the hospital to deliver it. And, believe me, gentlemen, that this virtue (for it is a virtue) of punctuality in a lecturer is a most important point, for though it will not redeem deficiencies, yet its absence will often neutralize all the excellences of the best of lecturers. If a lecturer be unpunctual and irregular his class will be small, a just penalty for these shortcomings. It is perhaps rather hazardous for me to dwell on these points so long as there remains any danger,—that I shall afford an illustration, on the wrong side, of the advantage of punctuality and regularity.

It would have been perhaps more judicious for me to have been warned by an ancient Latin proverb, which was levelled at those who created future dangers for themselves. The terms of the proverb have escaped me, but it was founded on the circumstance, that from the mistletoe which birds had propagated, by dropping its berries on the boughs of trees, the Romans prepared their bird-ensnaring bird-lime. Yet, if I noticed Mr. Adams' excellences at all—and I could not begin this course with decency without doing so—it became indispensable to speak in terms of praise of his remarkable punctuality, and thus to run the risk of suffering hereafter from those comparisons which, as Dogberry observed, are "odorous." Nor could I omit his sympathy with students. Mr. Adams was always popular with students because he took an interest in them, was always anxious, if possible, to assert their rights and privileges, and never held himself haughtily aloof from them, as if placed on a pedestal above their reach. It is needless for me to dwell on these topics. Fortunately Mr. Adams is not lost to us, but holds a position which few men have obtained more deservedly—that of Examiner at the College of Surgeons—a position in which his sympathy with students will still be manifested. But what, gentlemen, can be a severer commentary on the present mode of election of Examiners at the College of Surgeons than that a man like Mr. Adams, versed in anatomy, physiology, and surgery, a first-rate lecturer, fully conversant with what a student who presents himself for examination ought to know, and qualified by temper and sympathies for the office, should only be elected examiner at the end of nearly forty years' service, after the prime of life is passed; and then elected, not so much on account of a merit which no one can gainsay, and which ought to have ensured his election twenty years ago, but because his qualifications are supported by the accident of seniority to other members of the Council? Yet such has been the astounding custom in England. A College which now comprehends 16,000 members of the profession has been governed almost up to the present time by a Council composed of the oldest of its Fellows, and this venerable Council has elected as Examiners the oldest of its Members; and these "potent, grave, and reverend" Councillors and Examiners conjoined, have remained in office until death has removed them, and created vacancies for other expectant elderly gentlemen, in rotation, to fill till they too are ready to pay their debt to death. If such an arrangement had come within the scope of a Dean Swift's experience, or the experience of a Junius, what a satire might have been written! It may be said that things are better now. They are, indeed, altering for the better, but progress is slow. Still prevails the vicious custom of the Council of the College electing its own Members Examiners—seniority and age still have too much weight—the tenure of office, nominally limited, may be virtually unlimited—and the Examiners still examine indiscriminately in all the subjects of examination. Happily the profession is awakening to the evils which flow from this system, on which I have touched here out of justice to my colleague, whose election was not fairly treated at the time in a medical journal, and in the hope that at a later period of your career you will be led to take an intelligent interest in medical politics, for the purpose of upholding the dignity, honour, and chastity of your profession. Thus, then, gentlemen, I have become the sole occupant of this chair, and responsible for the whole of the anatomical course. In entering upon its duties I deem it advisable to indicate to you the views and aims which I shall place before myself, as well as the difficulties with which I have to contend in the treatment of my subject. The difficulties are many. This class is composed of two different sections of auditors. There are the first-year men—the freshmen—who presumably know nothing of anatomy, and have to be initiated into the mysteries of the human frame; and there are the second-year men, whose eyes are fixed with the unfaltering steadfastness of devotees on "the first at the College." The freshmen require to be fed with milk, and the second-year men with strong meat. If in his discourse the lecturer supplies only milk to the freshmen, a bitter cry of starvation goes up from the second-year men; if he distributes only strong meat to the second-year men, the freshmen loudly complain of indigestion. If he endeavours to divide and distribute the aliment, now giving milk, now strong meat, he is apt to dissatisfy all parties, and meet with the fate of the man who carried his ass over the bridge. This is the lecturer's first difficulty. His second difficulty is this. Among medical students, as among any other body of men, there is a large party of utilitarians. Our anatomical utilitarians are always inquiring "What do they want at the College?" The whole of anatomy, physiology, and, indeed, of medical science in general, is judged by this standard. You ask a man a question, and he cannot answer it. You would expect him to be concerned at his deficiency. Nothing of the kind. He not only doesn't know, but he doesn't want to know; he glories in his ignorance, in which he wishes to remain, because "they do not want that at the College." You may think I am exaggerating. No! gentlemen. I have been told more than once in this theatre when I have asked a question—and not at all an out-of-the-way question, or on an abstruse matter—"they'll never ask that at the College;" and I have really felt as if I ought to apologise for expecting a man to know some ordinary anatomical fact. Then comes a third difficulty. The lecturer on anatomy lectures with preparations and dissections before him, and from these he has to illustrate his text. To a small class, which can sit closely round him, it is easy to demonstrate as he proceeds, but it is not possible to show the finer parts to gentlemen at a distance. The lecturer cannot take the subject round in his hand; and though he can carry round small preparations, yet this occasions interruption to the thread of the discourse, and gives opportunity for the less staid students to indulge in a variety of ingenious, but improper and inappropriate, variations and combinations, which interfere with the necessary harmony. There are minor difficulties. One gentleman never learns anything from lectures; another goes to sleep; a third regards the lecture theatre as a place of amusement; a fourth declares that lectures are no use; a fifth remarks that it is given better in Gray; a sixth grumbles at having to leave his dissection to go into lecture; the seventh is sure he can read more in the hour than the lecturer gives him. A good many gentlemen dribble in late and disturb the class. These generally are they who love the uppermost benches and closely affect the wall, which often, I fear, possesses the ears which they seem to want. Now, with many of these small difficulties it is easy to deal. The playful man can be quieted, and the somnolent man can be aroused by a question on something recently imparted. The late arrival to-day will be in earlier to-morrow if the names are taken at the commencement of the lecture. The gentleman who learns nothing at lecture is probably one who never pays, or tries to pay, any attention. The intensely diligent student, whose dissection or reading suffers so very much, has a possible partiality, particularly strong at lecture time, for exercising the muscles of the leg on the foot-ball ground. With criticisms on the lectures it is not necessary to interfere. Criticism, if intelligent and respectful, is highly useful and conducive to the welfare of the school. Sometimes, indeed, adverse criticism is unfounded, proceeding only from those who will not listen to the voice of the charmer, charm he never so wisely; but then it falls to the ground, overborne by the voice of the diligent and attentive. At other times the criticism is perfectly just, and if it be uttered by all alike may be regarded as substantially correct. I do not give in my adhesion to the full meaning of the proverb "Vox populi est vox Dei," because the people are often blinded by a passion which finds no place in a celestial sphere; but after making all due deductions on such scores as this, I cannot but admit that what everybody says must be substantially true. Hence, gentlemen, it is as well for a lecturer from time to time to feel the pulse of his class, to see if it have that firm and healthy beat which betokens a well nourished organism, or any of the characters which indicate either insufficient nourishment or the presence of some source of irritation. *Your* wants must govern *my* ministrations. How am I to satisfy all parties? How am I to lecture so as to give the second-year men what they want, and at the same time not to be too brief or go too far for the freshmen? How am I to supply exactly "what they want at the College?"

Gentlemen, those among you who may have seen some remarks I made last March at the Medical Teachers' Association will remember that I then and there took my stand against compulsory attendance on second courses of lectures. Some reformers would at once sweep away altogether compulsory attendance on lectures. For certain reasons, on which I need not dwell at large, I think that it would be unwise to sweep away entirely the existing system before there is anything proposed in its place. I, for my part, think it safer to take the existing system, which comprehends compulsory attendance on lectures, and to reduce—and reduce *at once*—the compulsory attendance to those limits which common sense and convenience recommend; and then, having removed all practical grievances springing out of the extravagant, absurd, and injurious extent to which compulsory attendance has been pushed, we should be in a position to inquire without prejudice whether compulsory attendance on lectures or examinations was desirable at all, and, if it were not, whether anything should be substituted for it, or whether students should be permitted to enjoy perfect freedom to go in and out and find pasture as they pleased. It is not impossible or improbable that I should be found ranged on the side which is opposed to compulsory attendance on lectures; but however that may be, I consider it wiser and safer that students should be gradually emancipated. When emancipation is sudden, riot is apt to reign; but if effected in successive steps, time is afforded for the introduction of measures for the preservation of due order and decorum. Nevertheless, while these regulations last, we must conform to them, however inconvenient they may be to us both. I say to us both, because while they are inconvenient to you, they are inconvenient also to myself, inasmuch as they interfere with the adaptation of my lectures to the wants of those who are obliged to attend them. The students of the second year must sometimes be sent empty away, when I have to explain common things to the freshmen. For, indeed, I cannot but believe that it is my more particular business to make my lectures introductory to the study of anatomy, and to initiate the first-year students into its mysteries in an agreeable, and if possible, an attractive manner. The second-year men have surmounted, or ought to have surmounted, their early difficulties; they know, or ought to know by experience, where to find the knowledge which they require. The path has been smoothed, or ought to have been smoothed, for them already; and anatomy has become, or ought to have become to them, rather a matter of memory than of understanding. But with our freshmen it is different. Some, with unusual prudence, may have ground up a few bones, but probably the majority are ignorant of the very first elements of anatomy. Now, anatomy is not to all students an attractive or easy science. To some *dissection* is peculiarly repulsive. To others, whose memories are not very retentive, the task of learning anatomy seems like the task of Sisyphus. They roll the stone of anatomical knowledge a little way up the hill, but it rapidly descends, and all their labours must commence afresh. Anatomy is a science of hard and unfamiliar names, which require manifold repetitions before they become stored up in the nerve cells of the brain; it is a science composed of much fact and very little theory. Through this dreary wilderness the student requires a guide who will lead him along the right track until he is able to travel by himself. There is much that the teacher can do. He can turn the sesquipedalian and technical terms of anatomy into a means of assisting the students' progress. A very large proportion of the names used in anatomy are derived from the Latin and Greek languages, and with the derivations of these words the student should always make himself acquainted. He should accept the advice of Sydney Smith, and when he is unacquainted with anything he wishes to know, *immediately* consult the works of reference which he has by him at the time. If he lets the opportunity slip, the difficulty may recur to him when he has not the means of removing it.

Then, again, many of the names of muscles are what I may term scientific names. They embody substantial information and the most important information—namely, the origin and attachment of the muscle. Thus, the word sterno-cleido-mastoid is a scientific name. It at once tells you that the muscle arises from the sternum and clavicle, and is inserted into the mastoid process. The origin (sterno-cleido) is put first, and the attachment (mastoid) last. You should remember this fact, because it is not uncommon for students to make mistakes which the very words in their mouths would have enabled them to avoid. It would be well if all or more of the terms of anatomy were scientific terms; but "variety is charming," and some names teem with the poetry, some with the errors, and some with the fancies of the old anatomists, while others perpetuate the memory of their discoveries or descriptions. In illustration, I will merely name here the *pituitary* gland, the corpora *quadrigemina*, the *plantaris* muscle, the arbor vitæ uterinus, the alæ vespertilionis, and the Fallopian and Eustachian tubes, and Antrum of Highmore.

(To be continued.)

SYPHILITIC ULCERATION OF LARYNX.[1]

By John Morgan, F.R.C.S.I.,
Surgeon to the Westmoreland Lock Hospital.

E. D., aged forty, unvirtuous seventeen years, contracted a sore eight years since; two years afterwards got pains in the joints, and shortly after a severe ulceration of the throat and soft palate, which recurred from time to time, and for which she was treated in the Hospital. She has had two children since the formation of the sores, one of which lived till one and a half year's old, and died of some accidental affection; the other died young, but whether syphilitic or not cannot be ascertained. She was admitted to the Lock Hospital (having now her third, a healthy and fine child of three months at the breast) complaining of hoarseness and difficulty of breathing at intervals, particularly at night, is pallid, but not much debilitated, never had eruption, and shows no cicatrices of ulcers. She was put on tonic treatment—iodide of potassium and bromide of ammonium, and counter-irritation applied over the larynx.

On laryngoscopic examination, the epiglottis only could be seen studded with ulcers. The left lobe of the thyroid body was somewhat enlarged; but no enlarged glands could be felt. The fits of dyspnœa became gradually very urgent and sudden in their onset; during the intervals the symptoms were not by any means distressing.

On the forenoon of the 4th December, having just walked from one ward to the other, she was seized with a sudden fit of dyspnœa and died.

A *post-mortem* examination was made; the body was in fair condition; there were no marks or cicatrices.

On making an incision over the neck and sternum and dissecting down to the trachea, the veins were found intensely congested, the larynx externally was healthy, the lungs and heart were healthy also; about the root of the neck one of the glands of the right side was extremely dense, as hard as cartilage, and involved the pneumogastric trunk itself; the left recurrent nerve was surrounded by glands, small, dense, and closely adherent; the glands generally, about the root of the trachea were dense.

---

[1] Read before the Surgical Society of Ireland on Friday, December 11th, 1868.

On opening the larynx there were several ulcers of the epiglottis visible, and an extensive ulceration and necrosis of the upper rings of the trachea close to the cricoid cartilage. This had escaped notice during laryngoscopic examination owing to its position; the ulceration had destroyed all but the external layer of the trachea itself.

Mr. Morgan drew the attention of the Society to the extreme induration of the glands which involved the pneumogastric trunk on one side, and the recurrent nerve on the other, as explaining in some degree the suddenness and spasmodic nature of the fits of dyspnœa, as in the case of spasmodic croup, also to the character of the ulceration, exposing the cartilages the fragments of which were projecting into the larynx; and dwelt on the remarkable fact of the woman, though imbued so thoroughly with the syphilitic poison in its chronic or tertiary stage, having a healthy and untainted child at the breast.

COMPOUND COMMINUTED FRACTURE OF THE PATELLA—RECOVERY.

By **Francis McEvoy**, L.K.Q.C.P.I., L.M., M.R.C.S.E.

Medical Officer of Balbriggan Dispensary, &c., &c., &c.

D. M., a fine athletic young man, met with an accident whilst out on foot, looking at the Louth fox hounds cub hunting, it being their first visit in this country for that season. In attempting to jump from the top of a very high ditch and wide grip (the place from which he leaped being fully eight or nine feet from the bottom of the grip), which was cut through a kind of slaty, shingly rock, having a very sharp rugged surface at bottom, he was precipitated into it on his knees, in consequence of his foot catching in a brier.

In the excitement of the moment (a fox having been tallied), not feeling at the time that he was much hurt, he got up, ran a short distance, limping, and managed to cross a wall about three feet high, when his attention was called to his leg by feeling something warm running down it.

I was out that day, and just beside him when the accident occurred, although I did not see it. He asked me to look at his leg, which I of course did, and he showed me a cut, about three or four inches long, down the centre of the patella of left leg; the patella was also fractured. I bound it up and had him conveyed, as quickly as possible, to his uncle's house, which was the nearest, distant about half-a-mile.

I there examined him carefully, and found a wound, four inches long, down the centre of the left patella, which was fractured nearly in the centre, the internal half being very slightly larger than the external, which was again fractured into several fragments. The stone that inflicted the cut must have had a sharp, cutting surface, and also a wedge-like projection about the centre, as the outside half was starred, as you will often see a pane of glass when broken by a small, round stone or bullet.

Having thoroughly satisfied myself that there was no foreign body, in the shape of a bit of his pantaloons, stone, or clay, of any kind in the wound, I closed it with three or four sutures, and a couple of strips of adhesive plaster.

I improvised a capital splint and pad, which answered famously for the nonce, bound the leg firmly to it, procured a fine towel, dipped it in cold water, and applied it over the knee, with directions to keep it constantly wet during the night, and left him very comfortably, but dreading that the morrow would bring extensive inflammation and some of its concomitants—suppuration—which might entail amputation—nay, death, or, at the very least, a stiff joint, for which the surgeon is sure to get abused, aye, and that soundly.

On my visit next day, although I brought two dozen leeches, expecting to see the knee very much inflamed, I was agreeably surprised to find my anticipations groundless, the leeches not needed, and only as much inflammation as would repair the injury done, or that would naturally result from a simple incised wound.

I brought Macintyre's improved splint, placed the leg firmly in it, ordered cold to be still applied, and if the bowels were not moved ere morning, and he became feverish during the night, to have a dose of castor oil, or, if he objected to that, a rhubarb pill. Next day, at my visit, he was still better, although he had much pain in the knee, and was very restless and feverish during the first part of the night. After the bowels were relieved, he lost all pain, and slept well towards morning. Removed the dressing of adhesive plaster; the wound looked quite healthy, the greater part had healed by the first intention. The part that had not healed looked well also.

Fifth day, removed the sutures and substituted a linseed-meal poultice instead of cold water, as there was a slight oozing of matter from the wound (which was now reduced to about three-quarters of an inch in length), and slight puffiness about the knee, over the fracture.

Next day, knee better, swelling less, discharge healthy, and from this time forward he progressed favourably, and had not the slightest *contretemps* to retard his recovery.

In six weeks from date of accident he got out of bed, and, as I anticipated, with a partially stiff joint, which I considered might be much improved by time, use, and proper management. Directed him to sit on a table, with his leg and knee projecting over the edge, and, by working the leg up and down, the adhesions gradually became stretched, and he can now run, leap, play ball, and is one of the best fielders in his cricket club. Need I say more?

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,

Deputy Inspector-General of Hospitals.

Dysentery.

It may safely be asserted that in no disease so much as dysentery has the introduction of sanitary improvement exerted so marked an influence; the characters of that affection as it is now met with but faintly approaching those by which it was distinguished when it was the custom to crowd our soldiers together in imperfectly ventilated Indian barracks. In former days, this disease as it prevailed at some of our stations along the banks of the Ganges in Lower Bengal, was more fatal in its individual attacks than cholera, and numerically more prevalent than the latter; thus, while statistics show that during the thirteen years subsequent to 1842, the rate of occurrence of dysentery among our soldiery to have been 10·57 per cent. of strength, and that of mortality by it 11·47 per cent. of those treated, we learn by the Army Blue Book for 1866, that during that year the admissions by this affection in both its acute and chronic form were only at the rate of 3·80 per 100 strength, and of deaths 4·52 of those treated. I shall have occasion in the course of these notes to give some *cases* illustrative of the disease as it formerly prevailed among our troops in that country, and I venture to believe that whatever credit may now be justly assumed as belonging to the method of treating it, as compared with that formerly followed, yet the characters of the disease are now very different from what they previously were; improved sanitation having changed if not the type, at least the alarming severity with which in former days the malady made its attacks. When, for example, the 10th Regiment occupied the citadel of Lahore, soon after the subjugation of the Punjab, the men having been crowded together in rooms imperfectly ventilated and lighted, this disease prevailed so severely and extensively among them as to appear almost as an epidemic, at the same time that the officers, who were better accommodated, were almost exempt from it.

Much has been said in regard to the coincidence of hepatitis and dysentery in the same individual. I believe such connection to be neither invariable or necessary, although in persons saturated with malaria, as many become after long residence in Lower Bengal, and in whom the dysentery assumes the hæmorrhagic type, the coincidence is very frequent. In what is called inflammatory dysentery, occurring for the most part in the upper stations of the country, the two affections may occur perfectly independent of each other, and perhaps my own experience on these points may be taken as confirming the views expressed by Sir Rainald Martin. Not only do different types of the disease prevail at stations in different parts of India, but in different years at the same station; it may be assumed, however, as a rule, that in the north-west provinces the form most frequently met with is the inflammatory, and in the Gangetic stations the hæmorrhagic. In the former, active treatment, including depletion, calomel, opium, ipecacuanha, &c., has always been found most effective, the adjuncts being fomentations, hot water enemata, &c., and restriction of diet; while in the latter the indications all point to a different *régime*, and it is to be feared are not always met by young practitioners, who do not stop to consider the cases most suited for large doses of the last-named remedy, the re-introduction of which into practice has lately attracted much attention.

Were it practicable to institute statistics on a large scale regarding the prevalence in India and other hot countries of endemic diseases according to temperament, very valuable results would be obtained; thus in the selection of young soldiers to be sent abroad, army medical officers would have it in their power, in some measure at least, to select those who were thus shown to be the least susceptible to those diseases, and to reject those who are most liable to suffer from them. With this view I prepared the preceding abstract of deaths by dysentery among soldiers of the 10th Foot in India, according to temperament, as indicated by the colour of hair, eyes, and complexion.

I regret that I was not able to collect similar information in regard to the subjects of other *zymotic* diseases; and although the above numbers are too few in themselves to justify us in drawing any conclusions from them, yet I consider that the field of inquiry which they indicate is both an important and extensive one, and one which I trust will soon be investigated.

I would select the following cases as illustrative of the two forms of the disease as met with in India, premising that in the first class only does medical treatment appear to have much power. In the latter I have employed various methods, but regret to say with poor success; nor do I think that the disease, as observed at some stations, Dinapore for example, some twelve years ago, was amenable to treatment after its characteristic symptoms had fairly set in.

a. Inflammatory Dysentery.—Joseph McDonell, 10th Foot, thirty-six years of age, fifteen in India, had for many years been a hard drinker, although for some time previous to his present admission he had become more temperate in his habits. During his Indian service he had on two occasions suffered from dysentery, and for three months prior to his admission on 31st of October, 1858, the state of his bowels had been irregular, he having been treated on two occasions on account of diarrhœa. About ten days before he applied for admission, he began to suffer from pain in the abdomen, occasional calls to stool, especially for some time after going to bed. He complained of a constant sensation of coldness in the abdomen, and of borborygmi, and these symptoms increasing in severity, he began to strain when at stool. On admission there was tenderness along the course of the colon, and in the left iliac region; the stools were scanty, consisted of slime and blood like jelly, and were attended by much straining. A dose of castor oil and tincture of opium was administered, then three grains of calomel and one of opium, to be repeated every three hours, fomentations being constantly applied to the abdomen. After he had taken eight of these pills his sensations were reported as having improved, pain had diminished, and the evacuations contained liquid fæces. The pills were omitted, but the succeeding day the symptoms became aggravated, those from which he had at first suffered returning in an increased degree. On 3rd Nov. the pulse was 124, hard and wiry, calls to stool frequent, evacuations consisting almost entirely of liquid blood; there was much tenderness over the abdomen, great straining, but no heat of skin. He was now bled from the arm to sixteen ounces, which at once reduced the pulse to 100; leeches were applied to the anus, emollient enemata administered, and poultices applied to the abdomen. On the 4th the pain was less, pulse 84, soft; straining less urgent, but he felt very weak, and still the sensation of coldness in the abdomen continued; surface natural, tongue covered with yellow fur. Was now directed to have opium, 1 gr. m., pil., hyd. gr., ij., ipecac. gr., ij., every fourth hour, poultices and emollient enemata being repeated from time to time. On the 5th the mouth was tender, but an evident improvement was observable in all the symptoms; the evacuations were voided with less straining; consisted chiefly of mucus, only coloured with blood, but both in diminished quantity; there was less pain along the course of the colon, and it was specifically noted that no hepatic complication could be detected. At this stage the blue pill was omitted, but the ipecacuanha and opium continued as before. According to the report of the 7th, he had not been moved the previous night; the tongue had begun to clean at the tip; the mouth was better; pulse 80; all sensations improved. On the 8th he was stated to have been only once moved since the previous day, and in all other respects to have still further improved. He had now a dose consisting of ext. sennæ, ℈i.; pulv. rhœi, grs., x.; carb. magnes., grs., x.; aquæ, ℥i. His diet had been "spoon" with sago as an extra. From this date his improvement was progressive, and on 24th he was discharged to duty perfectly well.

---

* The above table is that alluded to in The Medical Press and Circular, Dec. 16th, 1868. P. 501.

I consider the above to be a typical case, both as to its symptoms and progress, and in regard to the treatment pursued; and although I do not purpose entering upon the consideration of the latter at length, I nevertheless, on looking back to the notes of this case, think the symptoms, as they successively arose, were directly checked by the remedies employed.

b. Hæmorrhagic.—It will be sufficient to describe the symptoms as they occurred, and briefly refer to the *post-mortem* appearances. John Brown, 10th Regiment, was admitted into the hospital at Dinapore, on 26th August, 1858. He had for years been a hard drinker, was a man of plethoric habit of body, and had only a few days before returned from pursuing the rebel Sepoys in the Jugdespore jungles, where he had been exposed to much fatigue, and almost constant wet. When admitted he was suffering from frequent purging of liquid matter containing a large proportion of bile; there was much abdominal pain and straining, and he stated that he had become attacked with these symptoms three days previously. The remedies employed failed to check them. On the 28th he was stated to have had much straining during the preceding night, with almost constant desire to evacuate the bowels. On that day, he having had a dose of laxative medicine (rhubarb and carbonate of magnesia), a free evacuation was obtained without pain, but the matter voided had the appearance of liquid blood, without shreds. There was no abdominal pain, skin was warm, pulse soft. On the 29th he continued to void similar matters, with some streaks of feculent matter. Between that morning and the 30th, he had been moved thirteen times; the nature of the matters voided continued as before; there was much thirst; tongue clean and moist; surface natural in temperature, but red and congested, as it had been from the time of his admission. Notwithstanding the various remedies that were administered, his condition went on from bad to worse. On 31st, the report of his case stated that he had been frequently purged; the stools like solution of blood, now containing some clots; the state of the tongue, pulse, and skin unaltered. The frequency with which he was moved increased, and the report of 2nd Sept. states that the evacuations had a distinctly cadaverous odour; the precise sensations complained of in the abdomen were a combination of those of emptiness and coldness, and of weight in the hypogastric region. He, moreover, complained of experiencing a peculiar feeling of sinking. On the 4th, to his other symptoms became superadded vomiting of matters similar to those voided. On the 5th, the frequency with which he was moved was still greater than before; the clots passed were of considerable size; vomiting was still more urgent; exhaustion had set in, and on the 6th he died.

In the *post-mortem* examination it was recorded that the body was covered with fat, the liver large, but showing no other signs of disease; the large intestine ulcerated in longitudinal oblong patches along its interior, its surface of a dark bluish colour.

◆

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Dr. Ogle's Cases of Abdominal Tumours.

(Continued.)

Case XXXVI.—*Abscess connected with disease of the vertebræ opening into the bladder; abscess of the kidney.*

Agnes W., æt. 40, a very fat woman, and rather yellow about the eyes, admitted Dec. 22, 1865. It appeared that, excepting bronchitis, she had had no illness up to four months before admission, when the legs began to swell. For two months she had complained of pain in the back, chiefly on the right side, accompanied by occasional vomiting, and it was thought then that she had abscess of the kidney. One month after this the dropsy diminished. Before admission she had shivering and feverishness, and had had a blister applied; and when admitted the pulse was 130 and feeble, and there was slight anasarca of the legs and ascites. The urine was like that from an irritated bladder, but contained no albumen. About two weeks after admission she had shivering, followed by sickness, but no pain. On Jan. 4th she suddenly passed about half a pint of pus from the bladder, which had not the appearance of having been long detained therein. Later on, the arms began to swell, but still no pain existed, excepting slight scalding on micturition. If any tender spot did exist, it was impossible to detect it, as she was so stout. The motions eventually passed involuntarily, and she became less sensible. She lost strength quickly, and no further change occurred until she died, Jan. 12th.

Post-mortem examination.—Emphysema of the lung and dilatation of the heart were found. The liver was very greatly cirrhosed, and all its fibrous tissue much increased. Behind the left kidney was a large abscess, which contained a considerable quantity of pus. This was traced down to the left side of the *bladder, into which it opened* by two or three small rounded apertures. This abscess proved to be connected with a small rough patch of diseased bone on the body of the second lumbar vertebra. There was a small circumscribed abscess in the right kidney, and both kidneys were vascular, having injected pelves. The bladder was vascular, containing pus.

Case XXXVII.—*Abscess of the groin connected with disease of the pubic arch; opening of pelvic abscess into the cavity of the uterus.*

Maria C., æt. 15, admitted August 16, 1865. For six months had suffered from pain and difficulty in passing the urine; and for some time had pain in the back. Six weeks before admission a swelling had formed in the left groin, and when she came into the hospital a fluctuating abscess was found in this part; after a time this burst over the crest of the left ilium, and much pus was evacuated. A purulent discharge also took place from the vagina, and continued to do so. She sank, and died February 16, 1866.

Post-mortem examination.—It was found that the abscess in the left side of the abdomen had originated in a carious state of the upper part of the left pubic arch, very near the symphysis, which was itself natural. The pubic arch on the right side, *at exactly the corresponding part* of the bone, was also similarly affected by caries, but to a very slight extent. The pus, in connection with the abscess, had burrowed all round the left hip-joint and upper part of the thigh. Parts of the ilium and of the lumbar vertebræ were rather rough, and, as it were, eroded; and pus was found to have ascended upwards along the left psoas muscle from the brim of the pelvis. Purulent fluid was also found to have passed through the pelvic tissues from the abscess, and to have found its way *into the cavity of the uterus* by an opening through its walls half an inch above the os. The bladder and rectum were natural: liver fatty. A few scrofulous tubercles were found in the uterus.

Case XXXVIII.—*Abscess in the abdomen in connection with disease of the pelvic bones.*

Louisa W., æt. 43, was admitted February 27, 1866, with a hard tense swelling in the lower part of the left side of the abdomen. It appeared that this had come on without any assignable cause three weeks before admission. After admission the swelling gradually softened and burst externally The patient was then affected by cough, and she began to lose flesh; the left leg became anasarcous. No cause of the abscess in the abdomen could be discovered, and she sank, and died May 8th.

Post-mortem examination.—Much fluid was found in the pericardium, and the lungs were emphysematous.

The abscess was found to have originated in carious disease of the crest and fossa of the left iliac bone, and pus had found its way thence upwards along the left lumbar region as far as the left kidney, which it partially surrounded. The bowels were matted together, but the abscess did not open into them. The iliacus, psoas, and quadratus lumborum muscles on the left side were almost quite destroyed, and the greater part of the second lumbar vertebra was exposed; a large reddish-brown clot existed in the left femoral vein, but there was little or no thickening of the sheaths of the vessels.

Case XXXIX.—*Rounded tumour in the abdomen, which proved to have been a calculus which had made its way out of the kidney into the intestines.*

Julia B., æt. 31, generally a delicate woman, was admitted July, 1851, passing much pus in the urine; she had been ill one month, the illness beginning with pain in the abdomen and loins, and arrest of the flow of urine: she had felt rather feverish, however, for a week or two before this. On admission, the purulent urine was acid; the pulse was 96 and soft; tongue pretty clean; she had much pain in the left iliac region (of two days' standing). The hypogastrium was hard and resonant, and a rounded tumour was found in the right side of the abdomen, having no resonance when percussed. She was very thin and had much night-perspiration. Under treatment she so far recovered as to be able to leave the hospital. It appears that six weeks after she left she was suffering from diarrhœa, and felt a " bearing down " in the bowel, and passed a calculus which was evidently not biliary, and when examined by Dr. Bence Jones, was found to consist of uric acid and oxalate of lime. Since that time she had been fairly well, excepting being subject to attacks of "biliousness," until three weeks before she was again admitted into the hospital, when she was seized with pain in the head and limbs, followed by sickness and severe pain in the abdomen, especially on the right side; she then vomited much, chiefly yellow material. When admitted February 4, 1852, the sickness was stayed; but the pulse was 130; the tongue whitish; and there was cough and expectoration. She lay chiefly on the back, with the legs somewhat drawn up; pain in the right side, chiefly below the diaphragm, being produced by coughing. There was rather more fine crepitation in the right than in the left lung behind, and the liver seemed to extend some distance below the ribs; though pain in the hypochondrium, which was hard and tender, prevented this from being clearly made out. In spite of treatment the pulse kept high, and the countenance very anxious. The urine was passed mostly with the stools, but when passed separately was found to contain pus globules and epithelial scales, and a slight amount of albumen. The lung-symptoms were treated, and for a time she improved. Night-sweats and hectic came on, attended by severe diarrhœa, and she sank, and died February 18th.

Post-mortem examination.—Old and recent pleural adhesions existed in both sides of the chest: the lungs themselves were congested; the heart natural.

On opening the abdominal cavity, extensive adhesions were found to exist between the stomach, the transverse colon, and the under surface of the liver; which organs were also adherent to the abdominal parietes. The transverse colon was also found to be tied down with tolerable firmness; and at it flexure at the right hypochondrium it was intimately adherent to the upper and anterior part of the right kidney. The kidney at this part, to which the bowel was adherent, was greatly softened, and dilated into a pouch, with a cavity communicating with the interior of the colon. The communication would admit of about a quill, and had rather hardened and thickened margins. In the pouch of the kidney were two or three small calculi of about the size of two peas each. This kidney was generally softened and increased in size; the other kidney was natural. The lining of the colon around and below the ulcerated opening into the kidney was thickened and congested, but nothing more.

The other organs were natural.

◆

MEATH HOSPITAL.

TUMOUR OF SUPERIOR MAXILLA.—SUCCESSFUL RESULT OF OPERATION.

(Under the care of Mr. Wharton.)

C. McC., a ploughman, æt. fifty-six, was admitted to the Meath Hospital on the 11th December, 1868. He had previously enjoyed good health, and stated that the members of his family had been free from disease.

In the early part of the previous October he remarked that his left eye began to run water, and that fleeting pains were often present in the same side of his face; he also suffered from pains in the left ear, and a stuffing sensation in his nose. A swelling then commenced on the left side of his nose, which gradually increased in size up to the period of his admission. During the growth of the tumour he suffered from frontal headache, and from occasional attacks of epistaxis, but never suffered from any fixed pain at the seat of the disease.

When admitted to hospital the tumour extended from the side of the nose, which it implicated, to the malar bone, and from the eye above to the angle of the mouth below. There was no dimness of vision, but the tumour, from its great size and protuberance, partially obstructed the sight. The skin covering it was moveable, red in colour, and of a temperature 10° Fahrenheit greater than that of the opposite side. It was of a firm, elastic feel to the touch, save at the bridge of the nose, where a distinct sense of fluctuation could be detected. In the diseased maxilla the teeth were much decayed—the first molar, the first premolar, and one incisor only being present.

Considerable doubt existed as to whether the tumour was of a malignant nature or not; however, Mr. Wharton after consultation, determined to operate, and the result showed that his judgment was correct, for a very careful microscopic examination of the substance of the tumour, made by Mr. Collis after its removal, showed that it belonged to the myeloid variety.

On December 21st, the patient having been placed under the influence of chloroform, Mr. Wharton proceeded to remove the tumour by means of the operation recommended by Sir. W. Fergusson making a single incision, commencing below the inner canthus and extending along the side of the nose, round the ala, into the nostril, and thence through the mesial line of the lip. The flap having been dissected back, he divided the bone above the alveolar process with a small metacarpal saw, and then with a bone forceps cut the nasal and zygomatic processes, and with the lion forceps removed the diseased mass, which was soft, and somewhat adherent to the neighbouring parts. Some small remaining pieces were then cut away with a curved scissors. The only artery requiring ligature was a branch of the facial, the labial vessels being controlled by Dieffenbach's forceps, and some small hæmorrhage in the cavity being checked by the actual cautery.

The cavity having been washed out with a 40 gr. solution of chloride of zinc, was filled with pledgets of lint moistened with the same solution, the strings attached to which were left hanging through the mouth; the lips were then drawn together by harelip pins, and the figure-of-eight suture, and the rest of the incision closed by means of the interrupted wire sutures. No dressing was applied, the anæsthesia was partially maintained, some brandy and water was administered, and the patient was removed to bed at 11.30 a.m.

12 *o'clock, noon.*—Some slight sanious discharge occurred. Patient felt well, but weak. Pulse full. 60. Beef tea and brandy and water in tablespoonfuls every alternate hour.

3 *p.m.*—Spirit lotion applied to wound; all going on well.

9 *p.m.*—Patient has slept a good deal. Slight oozing from nostril. Pulse regular, rate 96.

Dec. 22*nd.*—Has slept well during the night. Complains of no pain. Skin natural. Pulse full, strong, 78. Tongue clean, no febrile symptoms. Ordered arrowroot, brandy, and beef tea in small quantities.

Dec. 23*rd.*—Still doing well; no fever. Pulse 84.

Dec. 24*th.*—The patient making rapid progress. A very small degree of suppuration in the wound. The harelip pins were removed and the plugs of lint drawn out through the mouth, presenting no appearance of having lain in a suppurating cavity. A bread poultice to be applied to the eye, the lids having become agglutinated by the discharges.

Dec. 26*th.*—Patient progressing most favourably. The wound completely healed, excepting at the point where the ligature remained which was this day removed.

Dec. 30*th.*—The wound healed completely. Distortion of face almost disappeared, and the use of the eye restored, the infiltration of the lids having subsided.

January 6*th.*—The man is now quite recovered. A slightly depressed line marks the situation of the incision, and a very small amount of ectropion is the only deformity remaining, excepting, of course, some amount of paralysis of the affected side of the face, which is gradually disappearing.

The patient recovered without a single bad symptom, and required not even a single dose of medicine. On the fourth day after the operation he was enabled to walk about the wards.

◆

CITY OF DUBLIN HOSPITAL.

(Dr. Hewitt's Clinique.)

CASE OF SPINAL MYELITIS AND MENINGITIS TREATED BY THE APPLICATION OF COLD TO THE SPINE.

Fanny C., æt. thirteen years, was admitted October 2nd, 1868, suffering from imperfect and incomplete general paralysis. Had always enjoyed good health up to *September* 18*th*, when she complained of pain near the centre of her back, and shivering, the pain extending into her arms and stomach, being accompanied by twitchings of the upper extremities and lips, and towards evening becoming so violent as to necessitate her being placed in bed, and to cause her to cry aloud.

Saturday, 19*th.*—Was visited by Mr. Croly, who finding her bladder distended, introduced a catheter, and drew off a quantity of urine. Was ordered a mixture containing bark and nitric acid.

Wednesday, 23*rd.*—Still complained of the pain in her abdomen, and of intense itching in her head. Her mother cut her hair off. She passed water herself.

September 24*th.*—Pulse 100. Is able to pass water, but screams each time she does so. Catheter introduced, and about three ounces of thick urine, containing alkaline mucus, drawn off.

September 25*th.*—Extreme rigidity of tendon of biceps muscle in both arms, with hyperæsthesia, and the most acute pain, induced by even slight motion.

October 1*st.*—Pain on movement of her arms, if possible, increased in severity. She was placed in a warm bath by her mother, which, owing to the depressed state of the nervous system, produced vesication.

October 2*nd.*—Admitted to hospital.

October 6*th.*—Has passed a comfortable night. Has no power of using her forearms or hands owing to paralysis of flexor and extensor muscles. Passes her urine and fæces involuntarily. Came under the care of Dr. Hewitt, who ordered the ice-bag to be applied to the cervical and dorsal regions, with the following effect upon the pulse and temperature :—

	Pulse.	Temp.
Before application ...	106 ...	100·6
After	112 ...	101

The ice-bag produced the most marked effect in lessening the pain and rigidity of the muscles. Was re-applied after a short interval :—

	Pulse.	Temp.
Before ...	108 ...	100·6
After ...	104 ...	100·6

October 7*th.*—Was able to use her arms much better. Power over bowels and bladder improved. On passing a hot sponge along the spine no pain was caused. Electro-sensibility and contractility absent. Ice-bag applied for three hours at intervals :—

	Pulse.	Temp.
Before ...	92 ...	99·5
After ...	96 ...	99·8

After second interval :—

	Pulse.	Temp.
Before ...	96 ...	99·6
After ...	84 ...	99·3

Pulse has become stronger and more regular. Slight hyperæsthesia. Urine drawn off and found to be acid.

October 8*th.*—Appetite better. Increased power over arms and legs. Pulse regular, 104. Great contraction of biceps. Flexor muscles of arm slightly contracted. Improved expression of countenance. Urine highly alkaline, with a large deposit of phosphates after fourteen hours. Electro-sensibility and contractility of the entire body quite lost, except in face, where it is slightly retained. Was ordered the following mixture :—

℞ Tinc. ferri perchlor., min. xc.
Aquæ, ad ℥vj. ♏

Sumat coch. duo amp. ter die.

Bed sores having formed, were dressed with the following ointment :—

℞ Balsami Peruviani, ℥vj.
Vitelli oni unius. ♏

Ice-bag applied :—

	Pulse.	Temp.
Before ...	104 ...	98·2
After ...	110 ...	100·2

October 9*th.*—Hot and cold sponges were applied alternately along the spine. At first she could not perceive the difference, but on the repetition of the experiment she was able to perceive a slight variation in temperature. The battery was applied, but without any effect, electro-contractility and sensibility being still deficient. A catheter was introduced, and the urine which was drawn off was thick, viscid, and slightly alkaline, and when examined with the microscope was found to contain the phosphate of ammonia and magnesia.

October 13*th*.—Hands and feet cold and somewhat clammy, of a purplish red colour, which varied in intensity from day to day, having been a marked feature of the case from the outset, and serving to indicate the small amount of nervous force present. The pulse at wrist about 96, regular, but almost imperceptible. Legs drawn up by contraction of hamstring tendons. Bed sores dressed with ung. zinci oxydi.

October 21*st*.—Pulse 104, compressible. Surface less purple, and warmer. Pupils dilated. Increased power of muscular action.

November 2*nd*.—Much improved. Was ordered the following:—

℞ Ext. belladonnæ, gr. vj.
Tinc. cantharidis, ʒij.
Mucilaginis acaciæ, ℥ss.
Syrupi, ℥ij.
Aquæ, ad ℥viij. ♏
Ft. mist. sumat coch. ij. amp., ter in die.

November 16*th*.—Has continued steadily to improve. The surface of her body has lost much of its mottled appearance, and the rigidity of the flexor muscles is much less apparent.

December 18*th*.—Discharged. The muscular power of the lower extremities is completely restored, and she walks quite steadily. She has full power of retaining and voiding urine and fæces. The arms are still deficient in power, the right being the weaker. She can close the left hand firmly, and raise the arm of the same side above her head; but the right hand is utterly powerless, and she can only partially raise that arm. Her appetite is good, and her general health satisfactory.

◆

MERCER'S HOSPITAL.

SOME SELECTIONS FROM ACCIDENT CASES ADMITTED DURING THE MONTH OF SEPTEMBER.

By John Morgan, F.R.C.S.I,
Surgeon to the Hospital, and to the Westmoreland Lock Hospital, Professor of Surgical and Descriptive Anatomy, R.C.S.I.

EXTENSIVE FRACTURE OF THE RIBS AND CLAVICLE OF THE SAME SIDE—EMPHYSEMA.

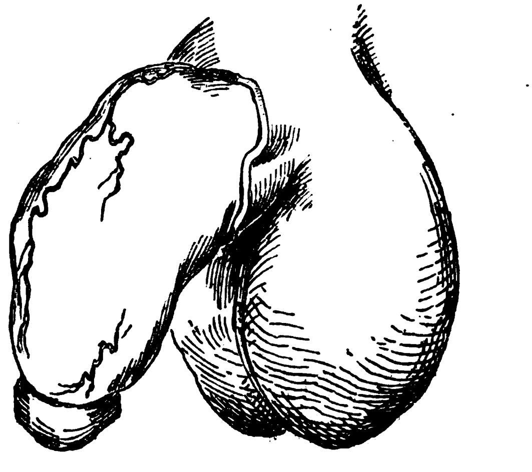
A slater, aged 64, was admitted on the 21st of September. He fell off a house thirty feet high, the ladder coming with him; he came on the left side with great force, and without anything to "break" the fall. He received most severe injuries, the third, fourth, fifth, and sixth ribs of the left side being broken in front of their angles; and also the left clavicle at its middle third. The man, though carried within ten minutes after the receipt of the accident into hospital, was found to be extensively emphysematous from the seventh rib up to the clavicle; the air making its way into the axilla passed along towards the back, which was highly emphysematous from the scapula to the level of the tenth rib. The patient being aged, and rather infirm for his years, was in an extreme state of prostration and greatly oppressed in breathing, and was already the subject of emphysematous lungs and bronchitis.

Malgaigne's method of strapping was at once applied over the broken side; he was given stimulants freely, and after much care and exertion he revived. On visiting him a few hours afterwards, the emphysema had not increased in the region of the ribs, but had very much so about the rest of the neck and the upper part of the chest. On careful examination it was found that the emphysema in this region was due to the sharp end of the fractured clavicle, and that its extent was momentarily increasing. The arm was brought well back and the fragments forward into apposition, straps of good adhesive plaster being coated around the emphysematous region.

There was a good deal of hæmoptysis, and the patient remained very prostrate and in a critical position for some hours. In the evening there was a good deal of tympanitis of the belly, and the breathing was distressed. A turpentine enema was given with good effect, and general stimulants administered. The patient gradually recovered without a bad symptom, and was discharged cured.

THE ENTIRE PREPUCE AND SHEATH OF THE PENIS REMOVED BY THE BITE OF A DONKEY.

A boy, aged 13, was feeding a donkey, when it made a snap at him, unfortunately catching the trousers and penis contained in its fold. By the violence of the bite, and the boy falling to the ground, it took off the entire prepuce, which was removed as neatly at the root of the penis as if done with the knife. The veins around the penis were exposed, but escaped being opened, excepting a few at the extremity, consequently there was comparatively little loss of blood.



The prepuce was found in the trousers, exactly like the finger of a glove, and the penis gave the subject for the illustration. Chlorinated lotion and rest were prescribed. After eight days the penis had a good deal skinned over, and the boy left hospital. Curiously, this is the third case I have seen of this accident.

PHANTOM TUMOUR SIMULATING PREGNANCY.

A strong able-bodied woman was brought in by the police at night, stating that she had been severely beaten, and, being far advanced in pregnancy, was suffering severe pain from being kicked in the belly, which there was evidence to show she had been.

On examination I found the abdomen enlarged to the size of full gestation, but the form and feel of enlargement was suspicious. I made up my mind it was a case of phantom tumour, and that the woman was malingering. I chloroformed her, and found the abdomen at once to fall and become flaccid. There was not the slightest tumour to be felt.

FRACTURE OF THE BASE OF THE SKULL EXTENDING INTO THE CAVERNOUS SINUS.

A fine lad of 19 was sliding down the balusters of a well staircase when he pitched over on his head; there was a plank laid across the well near the bottom, and on this it is supposed he came with full force. He was brought to hospital directly when found, probably fifteen minutes after the accident. He was altogether insensible, collapsed, and paralysed, and bleeding most severely from the right ear and nose; he had a cut and a large bloody tumour over the occipital region, low down near the neck, and the blood rushed in great quantity from the nose, correspondingly with every expiratory movement. In about two hours and a half he died, the quantity of blood lost being almost incredible.

A coroner's inquest was held and a *post-mortem* examination, when a most severe fracture was found extending from the occipital protuberance along that bone, going across the petrous portion of the temporal, which was broken in two places, from its harder structure breaking like marble; the fracture then entered the body of the sphenoid, the cavernous sinus was torn, and the cribriform portion of the ethemoid separated, the lesser wing of the sphenoid of the right side being nearly broken across—in fact, nothing could be more extensive, considering the site of the point of contact, which was at the occiput. The immense epistaxis was explained by the rupture of the cavernous sinus and the roof of the nose.

RUPTURE OF THE TEMPORAL ARTERY FROM DIRECT VIOLENCE.

A young man was cleaning windows and fell from two storeys down on the ground on the right side of the head and face; he was brought directly to hospital, somewhat insensible and collapsed, having a large tumour over the side of the head and forehead; this tumour was observed gradually to be enlarging, and on examination it could be found that the temporal artery had been ruptured, and was communicating with it, and the tumour almost momentarily increasing its size, already equalling an orange.

Hard pads were placed over the artery near its ruptured end, and the effusion circumscribed also by pads and a well-adjusted roller; cold was applied to the tumour, and the head placed in an elevated position. The circulation was thus controlled, and gradually the blood solidified and finally disappeared in about ten days, the patient having, beyond the shock, escaped from further injuries.

REFLEX IRRITATION SIMULATING A FOREIGN BODY IN THE LARYNX.

A boy, aged 4, who had been in perfect health, was brought to hospital by his parents in great excitement, stating that a few minutes before, a piece of brick he had in his mouth had disappeared, and that he was seized with convulsions, and they thought suffocating. On admission, the face was intensely congested; the respiration rapid and shallow; there were convulsions, alternating with severe muscular twitches; the resonance over both sides of the chest was equal, but there seemed less respiratory murmur on the left. The parents were clamorous in their assertions that it was the disappearance of the foreign body that caused the fits. Though the circumstances were suggestive, and some of the symptoms indicative of the truth of such an accident occurring, the rhythmic nature of the convulsive throes and the muscular twitching made me rather regard the case as due to some reflex irritation. I ordered a stimulating enema, had cold effusion sedulously used over the head and spine, the boy wrapped afterwards in warm blankets, and a sinapism applied along the spine and back of the head.

Hyd. c. creta gr. j., and pulv. jal. co. gr. x. administered every three hours. The child gradually recovered, the spasmodic attacks disappearing when the bowels had freely discharged a quantity of semi-digested matter.

CORRELATION OF THE VARIOUS PARTS OF THE PHYSICAL SYSTEM.

Among the curious facts in reference to the correlation of various parts of the physical system, which have never yet been explained, is a curious one in reference to cats, which, Mr. Darwin assures us, are almost invariably deaf, if pure white with blue eyes. Dozens of such cases have been observed, while the young of such cats, if they have the least bit of colour on their fur, invariably hear. The same is true if one of the eyes be not blue. Dr. Sichel, of France, observed one case when the iris began to turn of a darker colour; and, curiously enough, the cat at the same time began to hear. Kittens are entirely deaf during the first nine days, while the eyes were closed; and their eyes remain blue for a few days longer. While blind the loudest noises do not affect them. The experiment should not be tried by shouting near their ears, as they are extremely sensitive to any breath of air; but by producing any clanging noise, as by striking a pan or shovel.

EDUCATIONAL REFORM.—No. VI.

Strongly impressed with the belief that a reformed Medical Council should possess an absolute authority over the corporations and a general influence over the schools in all matters relating to medical education, we have traced many of the advantages which would result from this possession. Among the advantages specified were: the disappearance of schedules, and all the trouble and annoyance which they involve; the abolition of a number of conflicting and intersecting regulations and curricula; harmony between the general curriculum and the curricula for University degrees, as a result of which we might expect a larger number of candidates for University distinction; the classification and definition of the subjects of study; the cessation of compulsory attendance on lectures, as part of a central code, the alteration of compulsory attendance in kind, and the reduction of it in degree; the establishment of a single and uniform set of examinations for a minimum qualification to practise in the United Kingdom; the substitution of one title for the general qualification, in the place of a number of titles of variable and uncertain values; and the removal of all fragmentary qualifications. Moreover, in respect to our medical schools, the quality of the instruction would be raised; professors would be more efficient and better paid; a healthier competition would be engendered; a large amount of educational material existing in our workhouses, special hospitals, county hospitals, infirmaries, and dispensaries, which, for all educational purposes, are "unweeded gardens grown to seed," would be utilised; students would possess greater freedom in their choice of instructors, and obtain the full value of their payments; and schools would be obliged to adopt the best methods of instruction, and to direct the instruction more definitively to the ends in view. Looking over this catalogue of consequences, we cannot see any which would not be generally regarded as "consummations devoutly to be wished"; nor can we perceive that any are open to very substantial objection. It might, perhaps, be urged, with some show of plausibility, that the abolition of schedules, and the manumission of students in regard to attendance on lectures, would import disorder into our schools, because a useful and necessary check would be removed. But this would not be so, because, according to our plan, a student would still have to present, before each examination, a certificate signed by the chief authority at his place of study, and testifying that he had employed his time satisfactorily, and had conducted himself with propriety. This being the case, it is very evident that the individual schools could impose any conditions of signature which they pleased. They might demand attendance on lectures, or submission to class examinations, or to sessional examinations. Such conditions, of course, would be announced in the prospectus of the school imposing them. Some appear to have an objection to a public avowal of any kind of discipline or check, in the belief that it would prevent students from entering at the school which announced it. We are strongly of opinion that this is an entire mistake, and that parents and guardians like to feel that their sons and wards are under a moderate amount of restraint and moral compulsion. Human nature is weak, especially towards the termination of the teens, and unless there is an examination at the end of a session, the session is apt to be wasted, even against the desire of the defaulters themselves. We are no advocates for anything approaching to military discipline, but for some pervading attractive influence on the student, which, like the "guiding star, would gently lead him on"; and since we have urged the withdrawal of compulsory attendance on lectures, we cannot but recommend the substitution of the satisfactory passage of certain school examinations in each session, as a condition of signing the proposed certificate. These examinations would also answer another purpose. Unpopularity is often incurred by authorities at medical schools on account of alleged favouritism and unfairness in the bestowal of the appointments at the associated hospital. If all the students of a school had regularly to undergo examinations in the subjects of study, and were arranged according to merit, the results would give most valuable data as to the comparative efficiency of the candidates, and could be used to aid decisions on the bestowal of appointments. This would save the trouble of having a special competitive examination for every appointment—an arrangement in some respects desirable, but exceedingly inconvenient and irksome. The last advantage of this plan of regular sessional examinations would be that the classes of the professional "grinder," or "triturator" (to use the euphonistic phrase), would be thinned, and the extra money now spent upon that useful but depreciated functionary would be kept in the pocket.

There are some, we know, who object on principle to any kind of interference with the liberty of the subject. To the rules and conditions of educational establishments they cannot plausibly object, because no one is actually obliged to enter them; but they aim higher, and strike at the existence of licensing bodies and qualifying examinations. They assert that there should be free trade in medicine, and that anyone should be allowed to practise who pleased, and that there should be no examinations at all. Even if we agreed with these views we might reasonably be allowed to disregard them, as it is quite certain that they will never be adopted in this country. But we do not agree with them. It is the function of government to protect subjects in person and property, and government would not be fulfilling this function if it left the lives of its subjects at the mercy of ignorant pretenders. The qualifying examination is intended to exclude those who would be likely to prove unsafe practitioners. No expression of this fact could have been more modest than that made by Dr. Parkes, in his well-known speech at the Medical Council in 1864. He said then:—

> "I do not demand a high standard of examination. I do not demand anything more than that in the examinations it shall be seen that a man is not dangerous; if possible, that he should be gifted with such knowledge that will enable him to do good to the patients he is called upon to treat."

The "Register," unsatisfactory though its condition may be, is intended to go a step further, and inform the public who are the safe practitioners. Having done this, the Legislature will do no more; it will not permit men who have not qualified themselves to assume the titles of those who have, but it will not absolutely prevent unqualified practice. The public have the means of knowing the men who are worthy of trust, and if, in spite of this, they choose to be gulled and fleeced by harpies and quacks, they must take the blame upon themselves.

Another objection to examinations, of a different kind, was advanced by Mr. Jonathan Hutchinson, in his oration at the Hunterian Society in 1865. He affirmed that examinations interfered with the acquirement of professional knowledge, and were hindrances to the progress of science. There is some truth in the first part of this objection, because it so happens that at the present time men are obliged to submit to a great deal of useless instruction, and to acquire a great deal of knowledge which has little bearing on their future calling; but if examinations were made accurate tests of fitness for the medical profession, the remark would be no longer applicable. And with regard to science being retarded, it is not expected that men will make very great discoveries before they have been students of their profession for a longer period than four years. We believe that Mr. Hutchinson had partly in view the examinations at the University of London, over which he is of opinion that much valuable time is spent which might be better employed. For ourselves, we are not inclined to blame any man for aiming to obtain degrees which take so high a rank as those at the University of London. A medical man has not to consider only the advance of the healing art. He has his position to acquire and his bread to earn, and the advance of science must coincide with these all-important aims, or be effected by other agency for the time being.

We should not have dwelt so long on these objections, unphilosophical and untenable as we believe them to be, if we had not thought that they were valid for something beyond the things against which they are advanced. They are good in assisting to prove several points. They prove, in the first place, that, compatibly with the main end of the qualifying examination, "every possible latitude of choice ought to be allowed as to modes and places of education." A student ought not to be driven to any medical school, either in London or anywhere else, if he can obtain the required knowledge in his own way. It is conceivable that a man of moderate means might learn his profession at a very small cost, by taking advantage of casual opportunities, and teaching himself from books and public museums. He might even dissect in the country, if the law allowed him, in a country or village hospital;

and so long as he could satisfy the authorities as to his moral character, and his examiners as to his fitness for practice, he ought not to be bound down to arbitrary attendance anywhere. Such cases would not be numerous, but there would be others of a mixed nature, and the central rules should not stifle laudable aspirations. Secondly, the objections quoted prove the necessity of strictly adapting the examinations for the general qualification, to the end of providing safe and skilful practitioners for the public. Irrelevant knowledge should be eliminated from the requirements of the examining boards, and the ordeal made as practical as possible. Thirdly, these objections show the inutility, inexpediency, and hardship of having in the United Kingdom a number of different licensing bodies for the lower degrees, issuing regulations and curricula, and selling qualifications of variable values and repute. For the effect of this, as is well known, is to produce competition where there should be no competition at all. The great use of competition is to ensure the acquisition of the best articles at the smallest cost. The competition of the licensing bodies ensures the issue of a number of ill-qualified medical men at the greatest cost to the public. Mr. Ashe, in his very able "Carmichael Essay," has so well touched this subject that we must quote his words:—

> "We have to bear in mind that while, on the one hand, students of a high class are irresistibly attracted towards the quarter in which the examinations are of the stiffest character, the attraction being of course the high reputation of the license to be gained by passing the same, so that, like knights of old to some perilous achievement, numbers press forward to the trial, allured by the very difficulty it presents, and unfettered by the failure of many of their companions; yet, on the other hand, a constant stream of students of the lowest class sets in the other direction, that, namely, in which the examinations are easiest, in which the superior character sometimes claimed for them is known only to exist on paper in the schedule of requirements, or, it may be, in the questions set on the examination paper; but where, nevertheless, the difficulty of such questions is well known to bear no relation to the character and style required in the answers. We do not specify the direction in which this current sets; if there is any difficulty in ascertaining it the discovery may easily be made by inquiring of the worst qualified and most incompetent of the senior class where they purpose to seek their diploma; distances present but slight obstacles in these days; one thing is certain, there is no return current:
>
> "Vestigia terrent
> Omnia te adversum spectantia, null retrorsum"—p. 99.

This degrading tendency of the competition between the licensing bodies is only another reason for bringing the general qualification under the immediate control of the Medical Council. But if the Medical Council is to be autocratic, it is imperative that it should be made a thoroughly representative body. The question of the representation of the profession at large in the Medical Council is indissolubly bound up with the question of educational reform, and with the advancement of professional interests; and with the question of the representation of the profession is bound up a kindred subject—the reform of our Corporations. All these three reforms—reform of education, reform of the Corporations, reform of the Medical Council—are interwoven, and all three demand for their perfect accomplishment sustained and directed effort on the part of every "good man and true" within the ranks of the profession.

SCOTLAND.

EDINBURGH.

The Edinburgh Association for Improving the Condition of the Poor has been the means of doing a large amount of good among that class of the community. An appeal for funds has been made on its behalf. Dr. Littlejohn and Dr. Alexander Wood have published reports which give a faithful but frightful picture of the idleness, ignorance, beggary, drunkenness, debauchery, filth, want, wretchedness, disease, and preventible deaths occurring and accumulating in the hidden recesses of the city. It is with this great mass of evil that the above-named Association proposes to deal, in the hope of mitigating and reducing, if it cannot remove it.

JAMES DAVID FORBES, D.C.L., LL.D.

On the last day of the year just closed the late Principal of the United College, St. Andrew's, formerly occupying the Chair of Natural Philosophy in the University of Edinburgh, died after a long course of feeble and declining health. At a meeting of the Royal Society, held in the Royal Institution, Professor Playfair, M.P., pronounced a becoming tribute to his memory, and proposed that the Society should pass a vote of condolence with his widow, and express sympathy with his bereaved family. The motion was agreed to.

ROYAL INFIRMARY.

The contributors to this institution held their annual meeting on Monday, 4th January. There was a large attendance. The report was read, referring particularly to the number of patients treated and the state of the finances, after which a special report was read on the subject of rebuilding the Medical Hospital, in which it was said that the managers objected to change the site to the Watson Hospital ground. It was then stated that Mr. R. Matheson, H.M. Works, and Mr. D. MacGibbon, architect, valued the buildings and grounds of the George Watson's Hospital at £43,000, inclusive of the Wharton lane property. A number of gentlemen took part in the proceedings, and at length it was resolved to adjourn the meeting till Monday, 25th of January.

A collection from house to house on behalf of this Infirmary has been made in the Parish of Dirleton, amounting to £64. Contributions amounting to £120 had previously been made.

GLASGOW.

The annual meeting of the Glasgow Royal Infirmary was held yesterday—the Lord Provost presiding. The annual reports submitted showed that during the past year 5,314 patients had been admitted to the Infirmary, being an increase of 213 as compared with the number in 1867—an increase arising in the medical and surgical wards.

THE HEALTH OF GLASGOW.

The Medical Officer's Report to the Glasgow Police Board states that, during the fortnight ending December 31, there were 134 cases of typhus fever within the police boundary, against 136 in the preceding fortnight, and no case of small-pox.

ABERDEEN.—ROYAL INFIRMARY.

On Monday week a general Court of the president and managers of this institution was held in the Infirmary Hall for the purpose of electing a physician in room of Dr. Archibald Reith, who was regarded by last General Court as disqualified for re-election. A petition in favour of Dr. Beveridge, signed by 92 students, having been read, the vote was taken between Dr. Beveridge and Dr. Angus Fraser. The first-named gentleman was elected by 53 to 51 votes.

LEITH TOWN COUNCIL.

THE Provost read the returns of mortality from the report of the Registrar:—The death-rate during the month in the district of South Leith is about the average for the same month in previous years. In the district of North Leith, however, there is a very decided increase. Generally the health of the town is at present satisfactory, and there is no appearance of our usual fatal visitant at this season—typhus fever.

CUPAR-FIFE.

A MEETING of the District Board of Lunacy for Fife and Kinross was held on Thursday—Mr. David Gillespie, of Mountquharie, in the chair. Provost Hood, of Cupar, laid on the table a report on the asylum affairs during the financial year to 1st August last. From the report it appeared that the asylum was planned to accommodate 200 patients, besides the necessary staff of attendants, in all furnishing 250 beds, including twenty-four beds in two infirmary wards, intended for the isolation of patients attacked by other diseases.

BRECHIN.—NEW INFIRMARY.

YESTERDAY at noon a meeting of the Board of Management of this institution was held in the Town Hall—Bailie Scott in the chair. On the motion of Bailie Shiress, seconded by Mr. Ireland, a committee was appointed, with powers to meet with the medical men and arrange for their attendance at the Infirmary, and for a matron, and to furnish the necessary means for receiving patients; also, to provide for the opening of the dispensary for outdoor patients.

VARIOUS suitable contributions have been made in support of the Sick Children's Hospital, which, it is gratifying to know, has not been forgotten by a generous public.

◆

FRANCE.

THE FRENCH POST-OFFICE ARRANGEMENTS. THE MARSEILLES AND GENEVA POISONERS.

(FROM OUR OWN CORRESPONDENT.)

PARIS, DECEMBER 30, 1868.

WITH all her love of organisation, and boastful perfection of machinery, France might with great advantage take a leaf out of the book of those who rule in St. Martin's-le-Grand. When I read in my English papers some grumbling at the mismanagement of the English postal communications, I sigh for what seems perfection when I compare it with French administration. Let those who do not believe in the regularity of English posts come and stay a time in France. They will find their letters frequently delayed or lost, and their newspapers—confiscated? The Englishman is apt to conclude so, but that is doubtful in the majority of cases. I fear more frequently robbery on the one hand and carelessness on the other are responsible.

This week I received three days' *Times* by one post, having been pining for them during that period. Last week I got two copies only out of the six which I presume were duly issued, as I saw one of them at the Club. But bad as it is in Paris, that is nothing compared with the suburbs or the provincial towns. I have had much experience, and can conscientiously say that I know nothing worse than the mismanagement and improprieties of the French postal service. I see you have duly received one of my letters on the secret poisonings at Marseilles, but the other seems to have never reached you. It is rather annoying that what I thought the most interesting of all should have been written in vain. There were but few who were present at the court at Aix who would be likely to communicate with an English paper, and on that ground I flatter myself you would have been pleased to afford your readers a few notes. Like the papers sent you from Marseilles, my letter fails. The mention of those papers reminds me of one little circumstance that will show you the annoyance of French postal arrangements. In any town, to send a newspaper, you cannot, as you do in London, address it, stamp it, and drop it into the nearest office; but you must go with it to the general post-office (often involving a journey of a mile or two), deliver it into the hands of the clerk, pay him, and he affixes the stamp. Glorious liberty this, and a sure way to restrict the circulation of news! Often I wish to direct your attention to a subject in a French contemporary. It is easier to cut out the article and enclose it in a letter. This, however, is expensive, as only a quarter of an ounce is allowed for fourpence—the lowest rate between the two countries, separated from each other by a voyage of one hour and three-quarters! Long live the alliance of the Western Powers! This is international progress and amity!

I return for a moment to the secret poisonings at Marseilles to remark that, having looked over all the English papers received at the Clubs, I am surprised to find that not one seems really to have grasped the case with the clearness I expected. The facts are constantly misstated by the most accredited purveyors of correct intelligence, so that the conclusions arrived at are worth nothing. Never before have I so clearly seen the difficulties of one nation appreciating what passes in another. I hope, should any writer recur to the subject, he will first read the full report of the trial in the *Gazette des Tribunaux*.

I shall only stay to correct one misapprehension, as that refers to a professional witness. As I have told you, Dr. Alex. Martin strongly suspected poisoning in one case which he attended, and but for an accident to the apparatus of the chemist to whom he confided the analysis of some vomited matter, his suspicions would have become certainties, though, probably, too late to save the patient's life. The doctor was taken off his guard by the amelioration in the symptoms that took place at this time, and the impossibility of renewing the attempt at analysis. Also by the criminal summoning all the relatives, and appearing to act as if there were no occasion for concealment. As he said, all seemed open as the day. There is no doubt that the woman at this crisis saw the doctor's suspicions, and acted accordingly. The doctor exhibited the greatest emotion when he gave his evidence, and so far from appearing to those who heard him to deserve blame, was openly commended by the judge.

The Geneva Poisoner.—As you did not receive my remarks on this case, I may add that, horrible as it was, it cannot be compared to the Marseilles one. The convict was a nurse, and seems to have been possessed with an incredible mania for putting an end to the sufferings of her patients. Many consider her insane. She used belladonna, and seems to have acquired great knowledge of the action of that drug. Nine cases were brought home to her, and many other suspicious ones were not tried. The only motive assigned was the pleasure of watching the effects of the poison on her victims. No wonder so many consider her a monomaniac. Yet that is not half so horrible as the Marseilles wives who disposed of their husbands to enable them to carry on more easily their *liaisons*—and that, too, in some of the cases where the husbands imposed on the wives no more restraints than Frenchmen are accustomed to observe themselves. Husband and wife alike only nominally so; each seeking elsewhere the companion preferred, and regardless of the conventional custom of matrimonial faith. This is the state exposed by the trial—a state that exists in French society to an extent that Englishmen, with all their prejudices, do not exaggerate, and scarcely even imagine. Those who have lived a decade on the Continent begin to find out the utter rottenness of the bases of society.

Anæsthetics.—The new anæsthetic "laughing gas," mentioned in your columns some time ago, has been tried to some extent in this country also. At present the veterinary surgeons have taken it up, and are making some interesting experiments. I was told the other day that a horse had been kept under its influence for more than a quarter of an hour, and afterwards restored. The animal was intended to be killed by the nitrous oxide. It will certainly be a happy thing should such experiments as these take the place of some of the cruel ones of which the French veterinary school has been too fond.

Arsenic.—The value of this medicine in consumption is again on the *tapis*. The Academy trusted M. Hérard to report on a paper of Moutard-Martin's on this subject, and the report admits that arsenic is very useful in cases of phthisis where the stomach and bowels are in good condition. It is maintained by those who uphold this plan of treatment that arsenic not only influences the alimentary canal and gives tone to the general system, but actually impedes oxidation of tissue, and favourably acts on the mucous membrane of the lungs, by which it is said partly to pass out of the system. The experience of the Tyrolese arsenic eaters is of course brought forward in the argument. Arsenious acid in the form of pill is recommended as the most suitable preparation to employ.

Notes on Current Topics.

Intramural Burial in Cork.

An investigation has been recently held, in response to a petition from the Cork Corporation to the Privy Council, praying that eleven cemeteries in that city should be closed, in consequence of their insanitary state. The Commissioners appointed for the inquiry were Dr. Finn, of Cork, and Dr. Croker King, Poor-law Medical Inspector for the district. These gentlemen have recommended that, with the exception of the burial ground of St. Nicholas's Church, the churchyards shall be closed, but that the vaults shall be open for interments.

Mr. Baker Brown.

We learn that Mr. Isaac Baker Brown, of the London Surgical Home, has become a bankrupt. For the benefit of the uninitiated, or those of our readers whose recollection the circumstances have escaped, we describe Mr. Baker Brown as the inventor of the operation of clitoridectomy, and the obstetrical scapegoat of London. Possessed of great powers of observation and a fixed determination to "go ahead," no matter at what price the progress might be achieved, Mr. Brown found himself shortly in possession of a very lucrative practice and of the undying enmity of many of his brethren. This hostility, aggravated by the style of his writing and by the unpalatable theory on which his operation of excision of the clitoris was based, broke into a conflagration at last; and Mr. Baker Brown was, after a violent attack and a most unfortunate attempt at defence, expelled from the Obstetrical Society of London.

At that time we did not hesitate to take our stand, not with Mr. Baker Brown, but with fair play. We felt, and still believe, that the onslaught on him was that of a clique, and that it was pursued with little scruple as to its fairness; and, without expressing any opinion on Mr. Baker Brown's faults or merits, we opposed with vigour the attempt of an aggrieved multitude to crush out of existence a defenceless individual.

Whether Mr. Baker Brown's bankruptcy is a *sequitur* of his expulsion we cannot declare. Long before that occurrence his practice was extensive, and his apparent expenditure proportionately great; and it is said that the repudiation of him by his obstetric brethren had no considerable effect on the extent of his private practice.

Mr. Brown has offered his creditors a composition of 5s. in the £1, payable in instalments of 1s. 8d., at intervals of six, twelve, and eighteen months.

The approaching Army Competitive.

It has not yet been decided, as we learn on good authority, whether any appointments will be made to the British Army Medical Service at the next examination. The Senate of the Army Medical School have already decided on their examination, but are not themselves aware of the intentions of the War Office in respect of vacancies.

We believe that the intention to reduce a large number of Assistant-Surgeons to half-pay has been abandoned, and the reduction policy will probably not go further than to prevent any new appointments. There will be about twenty Indian appointments for competition, and if the English Service be closed it may be presumed that the competition for these will be severe.

Army Medical Reductions.

The press organs of the present ministry are as eloquent now in their advocacy of retrenchment in the army and navy as they were, a couple of years since, on the expediency and necessity of lavish war expenditure.

Mr. Cardwell's military reductions must be made palatable to the public and the House of Commons in anticipation of the dreaded Budget night, and, accordingly, all the stock arguments for saving money are, without much thought of their appropriateness to the existing time, and, indeed, without much sense or logic, put forward in the ministerial journals from day to day. Not a whisper is now heard of the well-worn phrases, "the surest guarantee for continued peace is to keep the nation on a level with the armaments of other powers," "the best economy is perfect efficiency," and all the dogmatic pleas for war waste with which the Palmerstonian extravagance was defended.

The *Daily News* of the 4th inst., in pursuance of its "duty towards its neighbour," in this behoof enumerated the directions in which economy might be effected, and notably advocated parsimony in the medical department of the navy.

Not at all on the ground that medical salaries would bear reduction—which statement would not face the proof —not that the army is over-stocked with doctors, for every one knows that the authorities have been at their wits' end for a sufficient supply; not for these, or any other reasons consistent with the maintenance of an army equivalent to those of other powers, does the *Daily News* advocate a reduction in the medical service—but because the proportion of medical officers is at the present moment, while the nations are in a condition of profound peace, more than is required for the health of the troops.

Surely, if the argument of the *Daily News* were brought down to its legitimate conclusion, the entire army, from the field marshal to the drummer boy, would be at once wiped out. Fighting men are, in times of piping peace, an absolute superfluity and a mere incubus on the country, and not even as useful to the country as the doctors who take care of them. Does the *Daily News* (in proposing that the excess of doctors, whose usefulness is undisputed, be dismissed when peace prevails) imply that other redundancies, admittedly of no use whatever, should be also got rid of?

The argument is simply puerile. Army doctors and fighting men are kept "in stock" because they may be wanted at any moment, and unless the *Daily News* declares for peace at any price, or shows us that Army doctors can be had at a moment's notice and, consequently, need not be kept on hand, it makes itself ridiculous in its endeavour to veil the unpleasant flavour of Mr. Cardwell's proposals.

Surgical Hangmen.

The *Somerset Gazette* refers to Dr. Carey's letter on this subject in our journal, and considers that the "profession is not scandalised, though the statement (that numbers had applied to the governor of the gaol for employment as hangmen) be perfectly true," as the *Somerset Gazette* believes it is. The editor certainly does not improve on the insult which such a statement conveys to our profession. Being called upon to withdraw or prove it, he fails to do either, but shifts the responsibility from himself and repeats the slander. It is a strange form of apology which tells a learned profession that whether the insult be true or not it is none the less suited to its members. The *Somerset Gazette* thinks that for a medical man to refuse his services to paupers because he is not paid is worse than to solicit the hangman's office. Truly a novel theory, and one of wide application, for if doctors be as bad as hangmen when they decline to work for nothing but charity, at what level does the *Somerset Gazette* place lawyers, attorneys, and all the world beside, whom the public is never so foolish as even to ask for *gratis* work? It is sufficient that medical men should be endlessly sponged on by the public, without their being condemned as of demoniacal atrocity if they object.

Tales about Tails.

No less a paper than the *Times* gives insertion to a letter describing the existence of a tail in the human subject, which is thus described by the correspondent:—

> In the autumn of 1855 I was sent, under orders from the Horse Guards, to superintend the volunteering of members of the Irish militia regiments to the regular army. One of the regiments I went to was stationed at Castlebar, and there I met a captain of the Land Transport Corps, then being organised, engaged on the same business as myself, but enlisting only for his own corps. On the first day of our competition the men discovered that his terms were better than mine, and one young man who presented himself, first for the Land Transport Corps and afterwards to me, on my asking why he had been rejected for the mounted corps, said, "Because I have a tail, Sir." There was a surgeon present who at once examined him in my presence, and I can vouch for the fact that he had a tail, and a most unmistakable one, it being about an inch and three-quarters or two inches long, thick at the junction with the body, and tapering to a blunt end.

We believe the only accurate record of a similar case is that published as follows, by Dr. Arthur Jacob, in the Dublin Hospital Reports:—

> In the course of last summer, a young man presented himself at the Queen's County Infirmary, seeking relief on account of a tumour which projected between the nates, and caused much inconvenience from its bulk, especially in the sitting posture. It had existed from birth, was about the size of the closed hand of a large man, and was situate upon the lower part of the sacrum, apparently involving the os coccygis. Upon its most convex part was an orifice through which the finger could be introduced, and passed round an irregular resisting body, which partly projected through this opening. The surface was covered by sound skin, furnished with a considerable quantity of hair. The operation of removing it was performed by my father. On dividing the external layer, it appeared that this was merely a pouch of skin, reflected inwardly, and embracing a cylindrical resisting body nearly six inches long, and thicker than the thumb. This cylindrical body was doubled upon itself, as if so disposed in order to fit in the pouch; it also was covered with true skin. This extraordinary production adhered firmly by one extremity to the spine, and upon attempting to detach it, the connection was found to be osseous; the bone, however, was so spongy that it yielded to the knife. The superfluous skin having been removed, the lips of the wound were brought together, and it healed satisfactorily, leaving the patient free from distress on this account.
>
> When the pouch was first divided, and the contained member fully displayed, its appearance was so characteristic, that no doubt was entertained of its being a real tail; which has since caused no small degree of merriment. When the part came into my possession, I made a longitudinal section of it from end to end, and found that it was furnished throughout with a bony core or centre, consisting of separate pieces, distinctly jointed to each other with perfect synovial capsules.
>
> That it resembled a tail in its external characters, I admit, but dissection proves that the bones which occupy the centre bear no resemblance to vertebræ, but, on the contrary, that they are such as might belong to a man's great toe; consisting of a tarsal bone (probably the internal cuneiform), a metatarsal, and phalanges. It, in fact, appears to be an example of that description of monstrosity which has often been observed in other situations, a rudiment or portion of an additional limb or extremity. This one is, however, remarkable from its consisting of but one series of bones out of the five, as well as from the situation which it occupied.

Death in a Police Cell.

Dr. R. B. Painter, who formerly was seven years Surgeon to the Police at Bow street, says, in reference to this distressing fact:—

"The great fault of the present system is, that for the sake, I suppose, of economy, the surgeon is not sent for nearly so often to the police-station as he ought to be; and that the inspector or sergeant on duty is the sole judge as to whether a given case requires the doctor, and is one of intoxication, illness, bodily injury, or what not; and this, although the discrimination between intoxication, apoplexy, starvation, fracture of the skull, or some kinds of poisoning, is frequently so difficult as to tax the skill of the most careful surgeon. And I hold that whenever there is the very slightest suspicion of illness or accident the surgeon should be sent for. I shall be told this is the rule, but I know, as a matter of fact, it is not acted on to the extent it ought to be."

It is said that the medical advisers of Prince Napoleon have ordered him to spend some time at Nice.

Great opposition is manifested by most of the parishes which have been ordered by the Poor-law Board to build sick asylums.

From the report of Captain Shaw, Chief of the Metropolitan Fire Brigade, we learn that they have been "called" to as many as 1,858 fires during the past year.

The death of Sir James A. Gordon took place at Greenwich Hospital, of which he was Governor, on Friday last, at the age of eighty-six. He is thought to be the last of the captains who served under Nelson.

Dr. Headlam Greenhow has been elected President of the Harveian Society.

The choice of the Obstetrical Society has fallen upon Dr. W. M. Graily Hewitt; and that of the Pathological

Society upon Dr. Richard Quain. The Epidemiological Society has elected Dr. Edward Seaton, Medical Inspector to the Privy Council, to fill the presidential chair.

The Treasurers of St. Bartholomew's Hospital have just received a large addition to the funds of this charity by way of compensation for a plot of ground taken by the Midland Railway Company. The sum awarded is said to be £45,000.

At the Royal Institution on Thursday next, at 3 p.m., Mr. Rupert Jones will lecture on "Protozoa;" on Friday, at 8 p.m., Mr. A. Herschel, on "The Last Eclipse of the Sun;" on Saturday, at 3 p.m., Professor Odling, on "Hydrogen and its Analogues."

Considerable doubt and uneasiness have been felt by some members of the profession as to the effect of the new Pharmacy Act, which came into operation last new year's day. We understand that it will not be allowed to interfere with the rights of the medical practitioner.

John Edward Johnson, Esq., who died on the 15th November last in the Chapel of the Foundling Hospital, has left to the Royal Hospitals of Bridewell and Bethlem, of both of which he was president, £1,000 in equal proportions; to the Corporation of the Sons of the Clergy, £1,000; and to the Foundling Hospital, £500.

◆

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. VII.

To be "the man in possession" of a house, as its occupier, is universally acknowledged, by the inexperienced in such matters, as a right foot placed securely on the stepping-stone to greatness, although at the precise time the acknowledgment may be made, a prowling wolf, assuming the outline and the garb of a modest and retiring lamb-like broker or his assistant, may be ambling near the door, waiting the drawing of its bolt or the raising of its latch, in order to enter to seize and to "bolt" with an amount of portable property sufficient to meet the claim of a relentless landlord or of an unsavoury cheesemonger. Nevertheless, the man in possession, as occupier, is regarded as the proprietor of a stake—often a tough one—in the street wherein he flourishes, and is considered one of a circle socially higher than the most stayed-up tenant of "flat" or of "pair," by whom he may be overshadowed. But, to be the actual *leaseholder* even at a high figure, of a "residence with coach-house and stabling for three," with rent paid up to coming gale day; with no odious rates nor taxes to fear; with name glittering in the sun on conspicuous panel of entrance door; with a practice of four hundred per annum (to be increased by habits of industry to double that amount)—*on paper;* with family relics, consisting of predecessor's widow, offspring, and appendices, in the persons of sympathisers and of servants on premises to "keep practice together"; with apartments luxuriously furnished for one's own use and occupancy; to remain so for some months, as per contract made and entered into, signed, sealed, and delivered according to law—in fine, with an old foundation which is being massively abutted, in order that a professional structure, firm, secure, and durable, may be raised, and from within whose very walls is to radiate in the unapproachable brilliancy of an animated meteor *that* metaphysical phenomenon mentioned in a former chapter. Surely, with so much within the range of tangibility, and with so much more within the kaleidoscopic ranges of hope and of ambition, in the *coup d'œil* that both presented, ample stimulus was afforded to set aglow any latent embers of pride a far less sanguine temperament than mine might have possessed. I was proud of my purchase, and considered I had sufficient reason to be so.

Domestic arrangements being thus satisfactory and complete, I next determined to become professionally perfect. Consequently I took an early opportunity to make a visit to the establishment of a celebrated surgical instrument maker, and to purchase there what I believed to be not only necessary, but likewise highly essential I should possess, in order to be in a position to meet the requirements of an extensive and of a diversified practice, then presumed to be within my very grasp. Of course the bill of particulars for those purchases was forwarded to my relation, who in due time remitted payment, together with an affectionate note to me, wherein was written: "I hope, my dear Quid, you *now* possess everything necessary for a fair start." I replied to my relative's communication, and said, "I am now, Sir, complete, and want nothing save your blessing, which I know will be heartily given to me, in order to make a good beginning."

My predecessor kept what is sometimes professionally designated "a close surgery," and I was informed that to see patients it was understood he remained at home from nine to eleven each morning and from seven to ten each evening, Sundays excepted, and visited his numerous patients at their residences between the hours of eleven each morning and seven each evening. I considered it very advisable, and a wise policy on my part, to tread in my predecessor's footsteps, and to adapt myself to the groove which he had formed in this daily arrangement of time; therefore I caused my programme to be publicly proclaimed, and to be wafted by the many winds of the establishment (relict and appendages, furious hurricanes and frightful tempests), and also by my slim boy in slippers, nicknamed by the *gamin* of the neighbourhood "Dr. Squirt" (on account of his connection with the high and honourable profession of medicine, and his position as Bright Buttons to the establishment, I presume), much to the annoyance of the boy, who, I am compelled to declare, at all times attempted to carry, with a degree of grave dignity not to be surpassed by even a Colonial Tiger, his patronymic heirloom, yclept Limbo Pod, and which was,—in consideration of his development, alas! faulty, and for the sake of brevity of expression, resolved by his immediate circle of friends and of relatives into the dissyllable "Boey."

"Quid rides?" asks a friend at my elbow; "Quid rides! Quid?" for I have laid aside my pencil in order to do myself justice in the performance. Well, my reply is one under which my friend winced, ere he suddenly snapped the silver chords of gravity, and joined me with a smile. It is this: I laugh at the tarnished state of rustless purity, *uncalled* for and unknown, in which many of those first surgical purchases still remain, honoured relics of gushing youth and inexperience; for, unfortunately for myself (fortunately *don't* say! for others), I never required to employ a tithe of them, nor do I expect ever to do so. Nevertheless I am proud of them, and open them up, and polish them up occasionally; and in doing it, mentally measure the span of years since their procuration, and if I laugh during the process, or now, it is not in the spirit the Roman tyrant Fiddled.

From many readers of these Pencillings, allusion to my primary display of professional resources may cause a tear to start, and memory to travel back to brighter and to happier days, when they, like me, put on for the first time the armour of our ancient and honourable profession. When parents or friends, perhaps long since wafted, let us hope, to a brighter sphere, affectionately presented to them the appliances to commence a professional career, as did my dear relative; to such I will say—"Let your tears flow freely, let memory travel whither it will, for tears reveal and are manifestations from hearts generous though impulsive, and it is wholesome, under all circumstances and conditions, to think of the past." Many readers of these Pencillings, too, may exercise the vacuity of laughter, and for a like reason; but whether grave, or gay, or glorious, and whether on the most exalted petiole amongst the branches, basking under the shade of the professional tree, or, perhaps, forcibly hurled by the blasting whirlwind of misfortune from its odours, its fruits, and its protecting influence—surely, all of us must feel an excusable amount of pride, coupled with a pardonable amount of vanity, in the contemplation of first professional achievements.

Quid Nunc.

◆

THE POOR OF LONDON.

A large meeting assembled at the Whittington Club, Strand, on the 21st ult., to consider the important questions connected with "The Present State of the Poorer Classes in the Metropolis, the Resources and Effects of Charity, and the Influence of the Poor-law system of Relief." Mr. S. Morley took the chair.

Dr. Stallard read a long paper. He said the first subject he should treat was "Pauperism." After remarking on the way in which the term had been used, and the consequent feelings which had been produced, he remarked that it was not with destitution merely we had to deal, for that, indeed, would be a comparatively easy thing to remedy, but with the violation of an essential social law, which holds every man responsible for his own maintenance in health and sickness and old age, and not for himself alone, but for his wife and children. He proceeded to make a variety of observations on the effects of the different modes of charity upon the recipients, and referred to the returns of the Poor-law Board, which showed that the numbers relieved in the half-year up to 1st January, 1858, were only 77,660, while those relieved in the half-year up to 1st January, 1867, amounted to 138,706, and it was seen from the monthly returns that the progressive increase was still going on. From these statistics he proceeded to facts, and said "The increase of 'pauper feeling' was shown by the fact that the people who availed themselves of the parish midwife and parish doctor had vastly increased, and by the neglect of home, as proved by the increase in infant mortality." Next he compared the different parishes, particularly that of St. George's, Hanover square, with Bethnal green, in this latter parish the physical condition of the people, he said, has degenerated more than in any other district, because the operating causes have had more time to play. I venture to assert, without fear of contradiction, that there is scarcely a native male adult in Bethnal green who is fit for military service. There are here hundreds of men who, being fit only for children's work, earn children's wages. Nowhere is the standard of comfort so low. There were 2,000 centres in London where enormous amounts were distributed, and at no one place could a deserving person be sure to obtain all the relief his case required. A person gets bread at one place, coals at another, soup at a third, clothes at a fourth, blankets at a fifth, wine at a sixth, physic at a seventh, and so on *ad infinitum*, but whether he gets what he wants at the time he wants it depends entirely upon his previous training in the habit of obtaining charity. Under this state of things it is scarcely surprising that the deserving starve to death weekly for want of timely help, and that the professional mendicant flourishes. In the case, for example, of medical relief, more than a million patients are annually attended gratuitously at the public hospitals and dispensaries, and over 200,000 more by the parish surgeons. At St. Bartholomew's Hospital, besides the regular patients receiving letters of admission, and of whom something probably is known, 110,000 persons are casually relieved. Will any man in the receipt of even a moderate income pay for such services out of his own pocket while he can have them free? Will he make provision for the time of sickness if he sees in the newspapers that so many thousands have been gratuitously relieved at this hospital, and so many more at that? This is the beginning of education in the pauper spirit, and needs to be restrained, for while medicine and medical advice are made so cheap and easy to obtain, there will be no motive for the establishment of provident and self-supporting institutions for a similar end. Passing on to review the Poor-law, he gave his confidence to the law passed in Elizabeth's reign, the principles of which enactment were that the rates should be levied:—"First, for setting to work the children of all such whose parents shall not be thought able to keep and maintain them; second, for setting to work all such persons, married and unmarried, having no means to maintain themselves, and who use no ordinary and daily trade of life to get their living by; third, for providing materials to set the poor on work; fourth, for the necessary relief of the lame, impotent, old, blind, and such other among them being poor and not able to work." He advocated a number of changes in the mode of dealing with the poor, and at length resumed his seat amid the cheers of the audience.

Other gentlemen addressed the meeting, and at length the discussion was adjourned for a fortnight.

ECONOMY DEPARTMENT OF SOCIAL SCIENCE ASSOCIATION.

A subsequent meeting was held on the 4th of the present month, at which Mr. Morley again occupied the chair. A long discussion took place on the subject of Dr. Stallard's paper, to which he replied at some length. The motion proposed at the previous meeting was agreed to, and a general desire was expressed that another conference should be called as early as possible.

Literature.

On the Artificial Production of Tubercle on the Lower Animals. A Lecture delivered at the College of Physicians, May 15, 1868, by Wilson Fox, M.D., F.R.C.P. Macmillan and Co., London, 1868.

No fact of greater importance, in our opinion, has come to light recently in scientific medicine than the discovery by the illustrious Dr. Villemin, of the Hôpital Val de Grâce of Paris, as to the production of tubercle by means of inoculation of septic matter into the cellular tissue of some of the lower animals. Dr. Andrew Clark, Mr. Simon, Dr. Wilson Fox, Dr. Sanderson, Dr. Marcet, and Dr. C. Drysdale have, as far as we are aware, been as yet the only observers in this country who have repeated the experiments of our learned Parisian *confrère*. The work before us is quite a splendid production. The drawings by Mr. H. B. Tuson and the execution of the plates by Mr. Ford, leave nothing to be desired. The great Dr. Jenner thought that he had rendered rabbits tuberculous by starving them; but this appears to have been an error on his part. Different other observers have attempted the inoculation of scrofulous matter from man on animals without success: but with the exception of the case of the illustrious Laennec, who, whilst making an autopsy of a tuberculous patient, punctured his own hand, and believed that he had inoculated himself with tubercle, facts are wanting as to inoculation being followed by any bad results. To Villemin, in 1865, then, is due the initiation in this matter. He only obtained positive results when he inoculated *tubercle* on rabbits. Matter, from other sources, proved inefficacious. In 1867, Mr. Simon appeared to confirm M. Villemin's views; and Dr. Marcet also was so converted to these doctrines, that he proposed to use the pulse of patients as a means of diagnosis of tubercular disease. Dr. Andrew Clark, on the other hand, stated that he had succeeded in producing the same results as those produced by inoculating tubercle by using other non-tuberculous products. Dr. Sanderson and the author of this work have both found that non-tubercular substances, introduced under the skin of guinea pigs, are followed by the production of a disease considered by them to be tuberculous. 117 guinea pigs and 12 rabbits were experimented on by Dr. Wilson Fox.

The most common local affection at the point of inoculation of tuberculous matter is found to be a cheesy mass, usually in a capsule; and sometimes cords of induration are seen extending, at variable depths, through the subcutaneous and muscular tissues. Cells from 1-2000th to 1-3000th of an inch in diameter are seen in many of the products of inoculation resembling epithelial cells. The axillary and sub-scapular glands are usually enlarged to twice their natural size. In the lungs we find scattered granulations more or less thickly spread throughout the tissue. The granulations do not project much from the cut surface. They are usually seen in the form of a semi-transparent hyaline margin with a cheesy centre. They rarely break down into cavities, and signs of pneumonia are very rare. They appear to originate in the bronchi, around the blood vessels, and in the tissue of the lungs. The granulations in the bronchi consist of masses of cells from 1-2500th to 1-3000th of an inch in diameter. The liver is greatly increased in size, and is heavier than natural; a tissue of a glistening transparent character is seen in it, occupying the substance of the organ to a variable extent. Under the microscope, the semi-transparent portions are found to consist of a new growth situated in the inter-lobular tissue. The spleen enlarges much; sometimes to two, three, or four times its natural size, sometimes large tracts of it are converted into a semi-transparent brittle tissue, resembling the liver or lymphatic glands. Changes are noticeable in the small intestines and cœcum. Peyer's patches are enlarged and prominent, and the peritoneal surface is injected. The patches on the cœcum are much enlarged; but the single follicles are less distinct than in the small intestine. Ulceration of the whole or of portions of the patch are not uncommon. The stomach is unaffected The mesenteric glands are almost invariably affected. Dropsy is very common in the peritoneal cavity, and is attributed by Lebert to obstruction through the liver. In the omentum are found granules, varying in size from a pin's point to a poppy seed, resembling the grey granulations found in tubercular peritonitis in man. Under the microscope, the granulations are found along the course of the vessels originating in their perivascular sheath. The cells are from 1-2400th to 1-3200th of an inch in diameter. The lungs were affected in fifty-nine cases out of sixty-four; the liver, in fifty-one cases. 117 guinea pigs were inoculated, and 58 proved tubercular; 12 rabbits also were inoculated. Tubercular affection is much more easily produced in the guinea pig than in the rabbit by inoculation. There is an absence of all tubercular meningitis in the guinea pig.

Virchow has pointed out the analogy between tubercle and lymphatic structures; both consist of round cells, of many of which the nuclei alone may be visible, agglomerated into little masses, like the follicles of lymphatic glands or the Malpighian bodies of the spleen, decaying early. Now, these structures on the lung present all the characters assigned to tubercle by Virchow; and our author thinks, and we agree with him, that the appearances in the liver also resemble tubercle in that organ in man. The cumulative force of the evidence as to these growths being tubercular is irresistible. The only known disease possessing the least affinity with this is leucocythæmia; but, in this disease, the growths are softer, whiter, and more milky than in tubercles. Nor is it at all identical with farcy nor pyæmia. Villemin's position, that tubercle is a specific disease produceable by tubercle alone, cannot be held, our author thinks, to be true; nor can the method of inoculation, he adds, be used as the test of the tubercular character of any pathological product, for four guinea pigs in whom vaccine-lymph was inoculated, and those inoculated with putrid muscle, and even one beneath whose skin he simply inserted a piece of cotton-thread, and also one of the four in which, following Dr. Sanderson's example, he inserted a seton, presented as intense and typical specimens of the disease as those on whom inoculation had been practised with the most typical grey granulations from the lungs or the meningeal vessels. Septic matter, he thinks, is required; and the cotton-thread acts by producing inflammation and blood poisoning. As to Lebert's experiment of injection of mercury and charcoal into the vessels which caused deposits in the lungs, these, he thinks, are not to be regarded as tubercle but merely local deposits. He adds an observation in which we fully concur, viz., that the effects of infection are more certainly produced by the inoculation of tubercle than by other substances. Hence, tubercle probably propagates itself; and Professor Niemeyer has been led to assert that tubercle of the lung may be a secondary consequence of unabsorbed pneumonias (Klinische vortröge).

Mr. Holmes, too (*Lancet*, 1865), stated that the removal of diseased bone prevents the formation of tubercle in scrofulous children. Hence, too, ordinary irritants, such as bronchitis or catarrh, may, as they appear to do sometimes, lead by irritation to the deposit of tubercle in persons predisposed to it. Guinea pigs and rabbits, although very liable to become tuberculous from inoculation, are not subject to the disease when living in ordinary circumstances. The author adds in an appendix that he has found that, in twenty-four guinea pigs, in whom, for the purpose of identification in another experiment, he had inserted a small piece of silver wire in the neck, three became tuberculous. This, he thinks, must either be the effect of a septic agent or of irritation. By these experiments Dr. Wilson Fox has rendered a great service to the cause of scientific medicine; and his work will, we believe, long be counted among the standard essays of this epoch.

Transactions of Societies.

DUBLIN PATHOLOGICAL SOCIETY.

December 12th, 1868.

Dr. McClintock in the Chair.

Dr. Lyons brought forward a morbid specimen taken from the body of a man, aged thirty-seven, who was admitted to the Whitworth Hospital on the 11th November. He was a labourer in a large porter brewery, and habitually drank large quantities of porter for some years. About a year ago, he began to suffer from hoarseness and a good deal of distress in breathing, referable principally to the throat. His health gradually gave way, and he then sought admission into hospital. He was suffering at the time very much from dyspnœa, there was a marked laryngeal stridor, and he was jaundiced to a considerable degree.

On examining the throat there was a great deal of pain felt on pressure over the os hyoides. It was evident also there was implication of the lung, but the most peculiar symptom about the case was the presence of jaundice. His eyes were well marked with the icteroid tint, and the whole surface of the body was also coloured. Appropriate treatment produced some relief, but he got no permanent ease during the last ten days of his life. The moment the dusk of evening set in his breathing became exceedingly difficult, and this was the principal source of his distress.

On *post-mortem* examination, very considerable and old-standing disease was found in the larynx, and on slitting it up the arytenoid cartilages were found to be almost all destroyed, there was a chamber occupying their situation on either side, the mucous membrane was a good deal thickened, the epiglottis and the lower part of the trachea were greatly engorged. The bronchial tubes were filled with viscid mucus of a bloody character to their utmost ramifications. There was also general engorgement of the whole lung, with patches of consolidation here and there, and little masses of tubercular deposit through the lung texture. It was on coming to the apex of the organ, however, that they found the most extensive evidence of its destruction. Here were large cavities, of old standing, communicating with each other, with a good deal of cartilaginous thickening about them. Both lungs were found to be similarly affected. There was nothing remarkable about the heart except patches here and there showing former inflammation. The large white patch was more obvious than usual, here and there were signs of pericardial inflammation, but there were no adhesions. The organ was rather small.

Mr. Lyons presented a well-marked example of what is called the Nutmeg liver; the greater part of the hepatic structure being affected, there was a good deal of general congestion. He, Dr. Lyons, would have expected in a case of such extreme tuberculosis of the lungs and also of the larynx, to find more or less of a fatty change in the liver, but he considered it to be one of the most noteworthy features of this case that it was in an opposite condition.

DECEMBER 19th.

Dr. Duncan remarked that the connection between loss of speech and cerebral disease had been attracting so much attention lately, that he brought forward the following case. A gentleman, sixty-five years of age, had been for thirty years an inmate of the asylum of Finglass. He was a person of eccentric habits, and laboured under marked delusions; but he was quiet, inoffensive, and generally enjoyed good health. He appeared to be in his usual good health on Thursday, the 17th, but on that night one of the patients happening to see him as he was about going to bed, casually asked him, how he was; he replied, "Not very well." Next morning when the attendant brought him a dish of stir-about, which he was in the habit of taking, his door was found to be locked, and the key inside, and there was no response to the knock for admission. The patient was observed to get out of bed and put on his drawers; he tried to open the door, but was unable to do so. When the door was opened, the patient was found to be paralysed in the right arm and shoulder. There was intelligence as far as we could judge. He appeared to recognise persons about him He was in the habit of taking snuff, and on handing him a snuff box he tried to take a pinch with his left hand, but there was not the slightest attempt at speech. He remained in this state until his death, which took place on Sunday, at half-past twelve, having had on Saturday night several epileptic seizures.

Autopsy.—The brain was of normal size and consistency, but there was a general opacity of the arachnoid, turgesemer of the whole volume, and effusion under the arachnoid membrane; the cerebral conjunctiva was more marked on the left side. Dr. Ward examined the brain along with me, and we found at the fissure of Sylvius a good deal of congestion, but nothing that we could call softening. What gave a considerable amount of countenance to the idea which locates the organ of speech to this portion of the brain was that precisely in that portion of the left hemisphere where Brocas' theory places that organ, there was distinct sanguineous effusion covering a space corresponding in size to a half-crown.

Mr. Flemming remarked that the diagnosis of disease of the breast, both in males and females, was very obscure, and not unfrequently tumours there situated were pronounced to be malignant when they were not so. The following case, which he now brought before the notice of the society, would serve to exemplify this fact. About three years ago, the wife of a farmer, between fifty and sixty years of age (who had had several children), of medium stature and full habit, applied for a consultation as to the condition of her left breast.

On examining the breast, a large tumour, whose growth had been very slow, was found, occupying the entire lower half below the nipple, with which, however, it was not identified, neither was the integument adherent to the tumour. At one special point the integument had a dark appearance, and a distinct sense of fluctuation was felt in that situation. In consequence of the enormous size of the breast and the condition of the woman, it was not deemed prudent to remove it, but an exploratory operation was made, and from four to six ounces of fluid were removed of the colour of brown sherry, and perfectly transparent; the density of this fluid was 1·020, it contained a large quantity of albumen, some cholesterina, but no pus. The swelling considerably subsided, but it was quite obvious that the portion of the cyst lying in contact with the breast was solid. The woman then returned to the country, and remained there. She called upon Mr. Fleming again that morning, and gave the following history. About four months ago she felt uneasiness in the tumour, and from that time it continued to increase in size. It occupied its old site, and the nipple was not connected with it. He again punctured it, and removed a considerable quantity of fluid, not less than six ounces, of a deep coffee colour, but otherwise its specific gravity and chemical constitution were identical with that removed on the first occasion. Here it might have been imagined from its appearance that the tumour was malignant, yet it was quite obvious from its history that it was not so, and that this palliative treatment was the proper expedient to adopt. The removal of such a large tumour might implicate the life of the individual, quite apart from the fact that such a formidable operation was not necessary under the particular circumstances of the case.

These se ro-cystic tumours of the breast occur in the male as well as in the female, and require great care as well as caution in their diagnosis. The general health in such cases is unimpaired, as in the present case.

Mr. Eames exhibited an example of rupture of the heart, the interesting feature of which was that it occurred at an unusual place, not at the apex but near the base of the left ventricle. The man was aged seventy. He was of general good health throughout his life, but for a week or so previous to his death he had been ill with a chest affection, for which he had been under treatment at one of the city dispensaries. On the Sunday previous he was missed from his house, and was found lying in the water-closet in a state of syncope. He was removed from that, and the treatment under which he had been was continued. On a day or two afterwards when walking across College Green, he fell dead. The pericardium was found full of blood, and the heart ruptured.

The rupture was of large size, admitting freely the index and middle fingers. The direction of the lesion was downwards and forwards, from within, outwards; so that the fingers passed in the opposite direction, from without, inwards, immediately entered the aortic orifice. The muscular structure of the heart was soft and flabby, having undergone extensive fatty degeneration. The valves were healthy.

THE SURGICAL SOCIETY OF IRELAND.

(Concluded.)

FEMORAL HERNIA.

Mr. G. H. **Croly** said that about five weeks ago he was summoned to visit a lady who had been vomiting the entire day and from the evening before. He questioned the patient as to whether she had a rupture or not. She was not aware, however, of the existence of any tumour in the groin, and she attributed all the vomiting to one of her usual bilious attacks. She stated that she was three months pregnant. He was struck by the peculiar character of the vomiting, which induced him to think that she had strangulated hernia. On examining the left groin he discovered a tumour not larger than the smallest sized filbert. It was not painful to the touch. The patient said, when he drew her attention to it, that "she did not attribute any of her nausea to that little lump; that she had frequently had bilious attacks and always had great difficulty in getting the vomiting checked." He at once gave her a turpentine enema, and applied ice to the tumour. He then left the house and said that he would return in a few hours to see her. On his doing so, he found that the symptoms were not relieved, there was pain in the umbilical region, the vomiting continued, and the pulse was accelerated. He attempted the taxis with great gentleness. The tumour, however, was firmly fixed, and having a great objection to the taxis he did not persist with it. He suggested a consultation, and the husband then wished for the opinion of the distinguished President of the College, Mr. Porter. Mr. Porter having arrived, he agreed with him (Mr. Croly) as to the propriety of immediate operation. As the patient apparently was not ruptured until 5 o'clock on the evening before, and had never worn a truss, he considered the hernia a recent one, and decided on performing what is known as Gay's operation for femoral hernia, which he accordingly did, the patient being under the influence of chloroform. When a few fibres of Hey's ligament had been divided, the hernia immediately returned. He closed the wound with sutures, applied a compress, and placed the limb in a proper position; he also directed opium, and ice internally. In two hours afterwards the bowels were moved naturally. The wound united by the first intention, and the patient had had no bad symptoms afterwards, and made an uninterrupted recovery. He should be glad to hear the opinions of the members of the Society as to the advantages of Gay's operation as contrasted with the ordinary mode of opening the sac. This was the first occasion on which he had performed Gay's operation. The reason he performed Gay's operation was, that as there could be no adhesions in so recent a hernia, he thought it would prove successful. The more he saw of hernia the more convinced he was of the necessity of avoiding the taxis and of operating early.

The President was present when this operation was performed, and he had never seen anything more successful or rapid than the return of the intestine as soon as the stricture was divided. He believed now-a-days most hospital surgeons avoided opening the sac, if possible. It was the operation that came nearest the perfect taxis, getting back the intestine without opening the peritoneum.

Mr. Collis said that a very curious case occurred to him within the last few weeks. A woman was under his care with strangulated hernia. He performed, as he made it a rule to do, Gay's operation, and on coming down to Hey's ligament he divided it with ease. The patient was of a flabby habit, and the strangulation not very tight. On withdrawing his finger a black mass, of the size of a walnut, came away in his hand. The outside was smooth and glistening, and when divided it was cut likewise smooth, black, and looked very like mucous membrane in a state of gangrene. However, he knew he had not opened the sac, and on careful examination he found no opening into the abdomen. On examining the black substance with great care, it turned out to be a clot of blood. Dr. Barker, who also examined it, confirmed him in that opinion.

Professor Hargrave observed that he had been very much impressed with the importance of not opening the sac in operating for hernia. The idea was not Gay's, but Petit's. It fell into disrepute for a time, but was lately revived by Mr. Gay, who now got all the credit of it. If they looked into Cooper's work on hernia, they would find it was proposed to operate without opening the sac. Some years ago he (Professor Hargrave) published some papers in the medical press pointing out the utility of the operation. With respect to what Mr. Collis had mentioned about the clot of blood, he should observe that every hernia he had seen presented some peculiarity of its own. No two hernias were precisely the same, and the surgeon must therefore be prepared in every case to meet with something different from what he had seen before. Our Secretary, Mr. Richardson, had operated on a case of femoral hernia some time ago, in which the symptoms of strangulation continued after the stricture had been removed. He was satisfied that femoral hernia was more suited for the operation of opening the sac than inguinal hernia. He agreed with Mr. Croly that they ought to abolish the taxis altogether. It was not from operation that patients died, but from delay in having recourse to it.

Mr. Richardson said that in the case referred to by Professor Hargrave, the symptoms of strangulation, as he observed, continued after operation and death ensued. It was found at the *post-mortem* examination that several inches from the nipped portion of the bowel there were some small gangrenous patches, with great congestion of the bowel in their neighbourhood, to which he attributed the persistence of the symptoms of strangulation. There were other points of interest in the case which Mr. Richardson reported in his account of it.

Mr. Stapleton thought there might be a rule laid down for opening and not opening the sac. In early cases the intestine was not likely to be adherent; but when strangulation had continued for four or five or six days, the case was very different. In the latter case, he thought the safest course was to open the sac. But then the great danger occurred from the endeavour to free the intestine and return. He had known a case where the intestine had been returned, and where a fit of coughing had caused it to give way. When the hernia had existed more than twenty-four hours the less handling it got the better.

Mr. Stokes would be glad to hear from Mr. Croly what length of time the strangulation had lasted in his case? He was himself an advocate for early operation, but he thought it a wrong principle to lay down that in all cases the operation should at once be had recourse to, for he thought when the strangulation was recent they should try the taxis in the first instance. Many present might remember Professor Bruce having stated at the British Medical Association, at Oxford, that during twelve years he had never found it necessary to operate for strangulated hernia. He could only account for this by assuming that the persons who came under Mr. Bruce's care in Philadelphia had sought for his advice when the strangulation was recent. In all cases which had come under his (Mr. Stokes') care, where the strangulation was recent, he had been able, by putting the patient under chloroform, to return the strangulation; but he thought, when the strangulation had lasted eighteen or twenty-four hours, the less taxis they tried the better.

Mr. Tuffnell said that if the top of the finger were passed over the hernia it would tell the surgeon whether it was a fit case for operation or not, there being a peculiar elastic, tense, resilient feeling in the one case and a softness in the other.

Mr. Pollock mentioned a case of strangulated hernia in a woman, which he had first seen at 9 o'clock in the morning. Towards evening vomiting came on, and thinking the case one for operation he advised the woman to go into hospital. She refused, however, and resisted the advice of her clergyman, who had been requested to endeavour to induce her to do so. She got opium at home, and towards the latter part of the evening the vomiting got much worse. He told her to send for him during the night if she got worse, but she did not do so; and the next morning he tried the taxis and had the satisfaction of reducing the hernia.

Mr. E. Hamilton wished to direct attention to the importance of giving the taxis a fair trial under chloroform. He had a case in which the strangulation existed for twenty-four hours, and in which the taxis was tried with success. The patient was brought to the operating theatre and placed fully under the influence of chloroform, which he thought should always be done. He was then placed in the position for operation, and the hernia was reduced easily with the taxis.

Dr. Fleming said that in the vast majority of instances, as regards operative proceedings, more rapid decision was demanded in cases where the hernia was femoral. He did not say that in all cases operation should be had recourse to. He had seen many cases in which invaluable results had followed from treatment by large doses of opium. Dr. Kelly, of Mullingar, gave opium even in cases of femoral hernia in very large doses—two grains every second hour—and with excellent results.

Dr. White mentioned a case of hernia which was brought into Jervis Street Hospital under the care of Mr. Corley. Mr. Stapleton saw the patient. The first thing thought of was to use ice, but there being no ice to be had Mr. Stapleton suggested ether spray, and under the use of it the hernia was easily reduced. It had been strangulated for some hours before the patient was brought into hospital.

Mr. Croly, in reply, said that Gay alludes to Petit and others in his work. He was aware that Mr. Hargrave had written an interesting paper on the operation some years ago. There was one material difference between the operations as performed by Petit and Gay. The former dissected over the hernia and divided everything except the sac; whereas Gay cut on the neck of the sac only. In reply to Mr. Stokes, he had to say that the hernia had been strangulated about thirty hours, and that the patient was under the influence of chloroform when he tried the taxis. He did not believe in the influence of chloroform in these cases. He could bring before the Society notes of four cases of hernia, where, by means of ice and opium, and O'Brien's tube, he had succeeded in returning the hernia. He did not operate in every case, but in this instance the tumour was one of unusual tension.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Monday, January 4, 1869.

Dr. B. W. Richardson, President, in the Chair.

A short communication was read from Dr. Balthazar Foster, on etherized cod liver oil, that is, the addition of 10·15 or 20 minims of pure ether to every two drachms of the oil, which Dr. Foster had found less nauseous and more easily digested.

Dr. Oppert related two cases of lead poisoning, one of a patient who enamelled playing cards, the other of a man who glazed straw hats.

Mr. Henry Smith exhibited a patient upon whom he had 18 months previously performed excision of the knee-joint, the patient walked excellently, without the aid of a crutch or stick, and without a high-heeled boot.

Mr. R. W. Dunn narrated several cases to show that whatever treatment may be adopted, a woman who is infected with syphilis before the seventh month of pregnancy is very likely to have a syphilitic child, but after that time the child will be free from syphilitic taint.

Mr. Hancock read a paper on Perforating Ulcer of the Foot. He commenced by giving the history of a patient, aged twenty-four, who twenty years before was attacked with swelling and inflammation of the great toe. An opening formed, which continued to discharge. Five years subsequently the disease attacked the sole of the foot, and Pirogoff's amputation was ultimately performed, with a good result. The author then narrated other cases which had commenced as a corn on the foot, for which amputation by Syme's method was performed. He thought this peculiar affection had not been sufficiently recognised. M. Cloquet first noticed it in 1837, and subsequently MM. Boyer, Mazolin, and Nélaton had drawn attention to it. It commences as a phlyctœna on the pad of the foot, after which the dermis becomes implicated, and at last the subjacent bone. This is the order of the phenomena which have over and over again been found to occur. What was the disease? Was it one of the developments of scrofula allied to phthisis? Was it a variety of palmar psoriasis? Was it due to syphilitic taint? All writers agree that it commences in the sole of the foot, corresponding to the heads of the metatarsal bones, doubtless from the pressure exerted on the part by the weight of the body. It is evidently constitutional and hereditary, some of the patients alluded to having relatives similarly affected. The disease commenced at the anterior part of the foot, and the heel never suffered. The author concluded a most interesting paper by observing that as soon as a perforating ulcer of the foot was recognised it was better to remove the whole of the metatarsal bones by amputation than by using palliatives, which condemn the patient to a succession of painful disappointments.

A brisk discussion followed, and the meeting adjourned.

◆

Gleanings.

SPECIALISM.

The world at large should recognise, better than it does, the great fact that in true scientific medicine there is no secrecy of knowledge, and should be more cautious than it is in believing that this or that man has some special gift or information which less favoured brethren have not. It is quite true that there are men endowed with special gifts resulting from practice or knowledge; one man has a delicate hand and a strong heart for the performance of an operation, another man has not, and so far the particular man is to be trusted and rightly preferred in his particular way; but carried to an extreme, the fashion of the public to specialise all medical men is painfully absurd, and opposed to the best interests of the whole human family. To assume that one man is, what is vulgarly called "clever," (a term of positive insult to a man of true science) for a given malady, a second man for another malady and so on, is injurious alike to the profession and the public. It fills the professional man with false pride, and leads him from the contemplation of the body as a whole, and disease as a unity presenting a variety of phenomena, to the contemplation of phenomena individually and apart from unity. It impedes discovery—which must always be built on unity—because it divides thought, and nourishes dogma. It ruins the public judgment, because it tempts the most insignificant mortal into the belief that if he can only successfully inoculate the public mind with the assumption that he is specially wise on a given disorder, he can win on that assumption. And, lastly, it prevents men of natural broad and expanded views from cultivating their particular talents, and enshrouds them with the fear that if they give scope and character to their life, they will be considered, however accurate their learning, however sound their judgment, as too general in their aspirations, and too indefinite in their principles. In relation to this same subject, the world at large requires to be corrected in regard to the object it has before it, when it seeks the services of the physican or surgeon. Ninty-nine persons out of a hundred who go to consult a medical man never think of asking for knowledge, but are content simply to ask for what they call an opinion; nay, when they change from one medical man to another, they take the step again, almost invariably, not with the desire of knowing more but of getting an opinion more. This is fatal error, leading to inconstancy, caprice, and deficient earnestness of purpose. An opinion can be given by any one; knowledge can only be supplied by the learned. I am so poor an astronomer I doubt if I could calculate the time of an eclipse, simple as the problem is to the learned in astronomy; but if it would soothe the feelings of anyone present to have an opinion whether the inhabitants of the planets live exclusively on Welsh rarebits, I would undertake to give an opinion on that subject—particularly if the usual fee were remitted—as sound as could be given by Adams, Leverrier, or Herschel himself. I do not offer these remarks as against opinion based on knowledge, but only as showing the folly, so widely prevailing, of seeking opinion irrespective of knowledge. True it is that the profession itself, to a large extent, corrects this folly, because medical men, when they meet together, go direct enough to the question, not of opinion, but knowledge, and test and try each other with a severity which those outside the pale little comprehend. It would be better for the members of the public to imitate this example; and in hours of trial, before they throw the handkerchief from this physician to that, to return disappointed, as they constantly return to the physician who knows them best, to consider on what grounds they make the change, why one man should know more than another and what solid reason gossiping advisers have for upsetting relationships that ought to exist between the sick man and his conscientious adviser.—*Dr. Richardson's Address at the St. Andrew's Association.*

ABSORPTION OF PHOSPHORUS.

M. **Mialhe** departs from his former views of the absorption of this article through the agency of alkalies, and now assumes that its solution takes place in the fats which are present in the contents of the bowel. He concludes from this, that an apparently convalescent after a poisonous dose may suffer a relapse on taking nourishment (?). Phosphorus acts as such, and not in chemical combination; even phosphoretted hydrogen changing into phosphorus and water in the blood. From the above, we should enjoin abstinence from fatty articles on persons poisoned by phosphorus, and when we administer it medicinally use the oleaginous solution. (*Union Méd.*, 1868, No. 66.)

DEATH FROM HYPODERMIC INJECTION.

Lantesson reports (*Journ. für Kinderkrankheiten*, 1868, 217—525) that he saw a child die in a few moments with convulsions, after he had injected several drops of liquor ferri sesquichlor., for nævus maternus. Dissection revealed large coagula in the roots of the great vein at the heart, and in the right auricle and ventricle.

He supposed that a vein of some size was wounded, and that the astringent thus got into the general circulation, coagulated the blood, and finally produced paralysis of the heart. He recommends that the flow of blood into neighbouring venous plexuses should be prevented by pressure when we perform this operation.

NOURISHMENT BY ENEMA.

Dr. Runge, of Nassau, reports (*Deutsche Klinik*. No. 27, July 4, 1868) a case of œsophageal stricture, in which the patient was sustained 59 days by clysters of yolk of eggs, broths, and gruels. During the first eight days he emaciated rapidly, and complained much of thirst. Then came a stationary period. In the third week he felt neither hunger, thirst, nor pain; in the fifth week he could walk pretty firmly. The emaciation had increased very little, when in the eighth week an inflammation of the rectum supervened, which terminated his life in the beginning of the ninth week.

Dr. R. thinks the patient might have lived many more weeks, had the complication alluded to been obviated by the exercise of greater care in the administration of the injections.

CURARE.

Curare comes from Para, Brazil, and is made from the juice of the strychnos toxifera. A peculiarity of curare, also met with in other organic poisons, is that it only acts toxically when it reaches the blood channel; and is inocuous, even remedial, when introduced into the system by other avenues. Iodide of sodium is in Brazil spoken of as a certain antidote to this poison, and mingled in equal quantity, in solution, the former is said to prevent the action of the latter. (*Reise der Novara une die Erde*, Wien, 1864.)

HERPES ZOSTER.

Moers (*Deutsches Archiv für Klin. Med.*, IV. 249) reports a case of herpes zoster bilateralis of the lower extremities, which occurred in a child fourteen months old. The vesicles did not dry up as is usual, but ran into bullæ, as in pemphigus. The child fully recovered in five weeks.

WOUND OF PANCREAS.

B. G. Kleberg reports (*Arch. für Klin. Chirurgie*, IX. 523) an incised wound of the abdomen which exposed the pancreas. The protruding portion was amputated, and the patient recovered without any remarkable consequences.

NOTICES TO CORRESPONDENTS.

To Correspondents.—We would impress upon our numerous correspondents the necessity of making their lectures, Original Communications, or letters intended for insertion, as short as is consistent with the subject on which they treat. We find it necessary to intimate this to our many friends, in consequence of complaints continually reaching us from contributors, who are anxious to obtain an early publication for their papers.

In deference to the wishes of a large number of our readers, we intend forthwith to devote several columns weekly to *excerpta* from the best British and Foreign journals, in order to keep our subscribers *courant* with the progress of medicine and surgery in all parts of the world. As our correspondent also suggests, "It will then be a very readable and practical paper: variety is pleasing."

Matar.—The course of lectures has not yet been announced. We will endeavour to ascertain in time for our next.

Mr. Whitehead (Preston).—Thanks.

Dr. W. Clarke.—We are gratified with your expressions of approval, and will endeavour to pursue the same independent line of action that has won for us your support and that of so many other new and old subscribers. We are not above the suggestions of our friends.

R. J. Kinkead, A.B., L.R.C.S., &c.—Your paper on "Treatment of Phthisis Pulmonalis by Pancreatic Emulsion of Fat" received, and will appear in an early number.

"**Notes** on the Treatment of Favus," by H. S. Purdon, M.D., received. Proofs shall be sent in due course to the address given.

J. J. Johnston, M.R.C.S. Eng.—"Successful Treatment of Anthrax" if possible, in our next.

Dr. Jacob's "Lecture on the Eye," with illustrations in six colours, is again unavoidably held over till our next.

Infant Mortality.—Too long for the present pressure upon our space.

Foreign Degrees, and How to Obtain them.

To the Editor of the Medical Press and Circular.

Sir,

Please state where I can obtain copies of the conditions on which the degrees of either of the undersigned universities are granted:—

1. Gottingen.
2. Erlangen.
3. Heidelberg.
4. Tubingen.
5. Geissen.
6. Jens.

Is the degree of M.D. obtainable without residence in either or any? Kindly supply full information in your next.

Yours, &c.,

Inquirer.

*** The conditions under which degrees can be obtained from the universities mentioned are, we presume, only to be had from the managers of these several institutions or their agents. Some time since degrees were conferred without residence, and even *in absentiâ*, but since the refusal of the General Medical Council to register them, and the exposure of the abominable system by Sir Dominic Corrigan, the traffic has been somewhat checked. We believe diplomas are still granted in some of these universities without examination, and "for a consideration" *in absentiâ*, but they would fortunately be perfectly useless within these realms, and certainly not very honourable after one's name. They are to be had at a price in London at the present time.

Dr. C.—Thanks for your letter; the paragraph in the local paper to which you draw attention is beneath notice. We are not disposed to enter into an argument upon the ethics of the medical profession with an editor, or, as you very properly term him, a "Literary Smasher,' who opens his columns to servile abuse of an honourable body, and to the advertisements of obscene quacks, which are refused by every respectable journal. The admission of this latter vile stuff would *alone* stamp any journal with the character of its conductors.

◆

Death.

White.—On the 12th of October, at Wahgnuyah, Colony of Victoria, Australia, Thomas Edward White, L.R.C.S.I., youngest son of Thomas Warren White, Esq., Barrister-at-law, aged twenty-nine years.

◆

APPOINTMENT.

John Murray, M.D.—Medical Registrar and Superintendant of *Post-mortems* at the Middlesex Hospital, vice Dr. Cayley, resigned.

◆

BOOKS, PAMPHLETS, &c., RECEIVED.

Braithwaite's Retrospect of Medicine. Vol. LVIII. London: Simpkins & Co.

The Monthly Microscopical Journal. London: Robert Hardwicke.

Established 1848.
PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.
50, Lincoln's-inn-fields, W.C.

MR. J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. (King's Coll.), has always upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements and no expense incurred (except in special cases) unless a negotiation be completed.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

A prompt and just system secured a large measure of success to the General Partnership and Commercial Agency Business formerly conducted by him at his City offices; this has for some years been transferred to Lincoln's-inn-fields, and he has invariably adopted the same equitable policy in the more professional matters placed in his hands. Thus his experience in the management of large commercial undertakings, combined with his medical, scientific, and literary acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on matters of dispute between professional men, Mr. Langley has had great experience, and he can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation, and in which his awards have been made rules of her Majesty's Courts at Westminster.

Mr. Langley can also refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

MR. LANGLEY'S Quarterly List of Selected Practices and Partnerships for Transfer, in town and country, is now ready. Free by post for two stamps. Address as above.

Now ready, Second Edition, with considerable additions,

ADVICE ON BUYING OR SELLING MEDICAL PRACTICES, PARTNERSHIPS, &c. By J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c.—Free by post for seven stamps.

IN a pleasant town on the coast, within 100 miles of London, an old-established PRACTICE for SALE. The receipts are upwards of £500 a-year; patients consist of gentlemen, farmers, tradesmen, and visitors. Excellent Appointments yield about £100 a-year. Expenses under £80 a-year. The house, with land, garden, &c., is the vendor's freehold, but would be let at a moderate rental. Premium £600, a part of which may be left on security. Address, X 455, care of Mr. Langley, as above.

NOTTS.—For TRANSFER, a PRACTICE, easily conducted and without opposition, in a pleasant and picturesque locality. Appointments can be easily transferred. Receipts £350 a-year. Pretty cottage residence; rent £10. An efficient introduction given. Premium 200 guineas. Address, X 454, Mr. Langley, as above.

GOOD COUNTRY PRACTICE, with Appointments, for TRANSFER, in consequence of ill-health, Income £150 a year. Appointments about £75. No opposition within three and a-half miles. The village contains 1,200 inhabitants. Convenient house; rent £20. Excellent shooting in the neighbourhood. No assistant nor horse required. Premium £350. Address, X 453, Mr. Langley, as above.

LONDON, W.—For TRANSFER, with complete introduction, an old-established PRACTICE, held by the vendor for upwards of twenty years. Average receipts during last four years upwards of £1,300; last year £1,250; midwifery fees from £1 1s. to £5 5s. One brougham and horse does the work. A dispensing assistant employed. A valuable public Appointment associated with the Practice. Large house in complete repair, on beneficial lease; rent £150. The whole connection is transferable to an active suitable successor. Address, X 399, Mr. Langley, as above.

LONDON.—For TRANSFER, a well-established PRACTICE, realising between £500 and £600 a-year. House containing twelve rooms, with large garden, &c.; rent £48. No assistant necessary. Great scope for increase. Appointments £34 a-year. Address, X 338, Mr. Langley, as above.

PARTNERSHIP INTRODUCTION.—A doubly-qualified gentleman can be introduced to a good family PRACTICE, in a very pleasant town within easy access of the coast. The vendor retires in consequence of ill-health. The occupation of the house, which is a remarkably good one, is optional to successor. The receipts have recently declined, in consequence of the inability of the holder to attend to his patients, but the whole connection is believed to be transferable, yielding at present on an average about £500 a-year, and capable of increase to £1,000 a-year. There is no dispensing, and the patients belong to the upper classes. Address, X 376, Mr. Langley, as above.

COMPETENT ASSISTANTS Provided without delay, free of expense to the principal. No gentleman recommended whose antecedents have not been inquired into. Apply to Mr. Langley as above.

LOCUM TENENS can be despatched by an early train after receipt of letter or telegram stating terms, duties, and qualifications required. Fee 10s. 6d. Address Mr. Langley as above.

Lecture.

Introductory Lecture
TO THE
COURSE ON HUMAN ANATOMY
AT THE
LONDON HOSPITAL MEDICAL COLLEGE,

By Walter Rivington, M.S. Lond., F.R.C.S. Eng., &c.

Delivered Oct. 5, 1868.

(Continued from our last.)

Another way in which a lecturer may assist the students' progress in any particular subject is by making generalisations which shall give interest to the study, and so combining these generalisations or general facts as to appeal to the understanding or reason, by the enlistment of which the memory will be relieved of much of the burden which otherwise would be cast upon it. You will understand what I mean if I give you an example. All parts of the body have their uses, and the use of a part affords a clue to its structure. These are two general statements. Apply them to the liver, and see how your memory may be assisted by the combination of these with other general or common facts. The use of the liver is to secrete bile; bile is a highly carbonaceous fluid; all secretion takes place by means of cells, which have the power of taking from the blood the required materials; there is a larger quantity of carbon in venous than in arterial blood. These four common facts lead almost irresistibly to the conclusion that the liver is an organ composed of a number of cells, arranged in the most convenient manner for forming bile out of blood, which is brought to them by *veins* with which they must come into intimate relation. The bile, when formed, must be carried away, and so, of course, there are vessels—called bile-ducts—for the purpose. The liver must be *nourished*, and therefore it possesses an *artery*. Certain vessels—called lymphatics—are required here, as elsewhere, for collecting waste matter for further use—for gathering up the fragments, that nothing may be lost—and then to preside over the whole arrangement the nervous system, must be represented by means of bundles of nerves. Now, the whole difficulty in learning the liver is reduced to the exact arrangement of these various elements: the cells, the bile-ducts, the veins, the arteries, the lymphatics, and the nerves. The particular facts connected with each are not complicated or hard, and may be very easily explained in such a manner as to keep the reason still at work in assisting the memory. The most difficult matter to remember is the names of the veins and their branches; but here fortunately comes in the ingenuity of the maker of memoria technica, and aids you once again by constructing a word out of the first letters of the names which you have to remember.[1] With such helps as these you can readily understand and know all the chief facts in the structure of the liver, and having once learnt them, you have no right to forget them, because by the aid of the common facts which I have mentioned, your reason can, as it were, rebuild the liver in your minds. Thus, gentlemen, by a little management, and the adoption of a cunning method of instruction, a lecturer may shift a great deal of the burden of a subject from the memory to the understanding, filling the mind faster with knowledge, and rendering it less probable that it will be rapidly forgotten.

But after all that the teacher may do for the student there is much, very much, that the student must do for himself by sheer hard patient application. He must follow the advice of Dr. Johnson, and "sit down doggedly" to his work. He must have a set of bones of his own, and eye them, and feel them, and mark all the irregularities of surface, and all the peculiarities of contour. He must follow the description of them painfully with his Ward, his Holden, or his Gray. He should rise to the level of a former beadle at this College, who could recognise blindfold the small bones of the hand, and even tell the side to which they belonged. This would have delighted the heart of Vesalius, who insists that it is the student's duty to know the bones by touch.

---

[1] The word Pilish, formed out of the first letters of the names Portal, Inter-lobular, Lobular, Intra-lobular, Sub-lobular, Hepatic. The word Pilish will probably adhere to the mind of the medical student more readily in consequence of the association of Piles and congestion of the portal system of veins. Other such names are familiar to students and teachers. In addition to the above and several others, I have formed for the remembrance of the surfaces of the orbital process of the palate bone, the word Moses, which represents the Maxillary, Orbital, Zygomatic, Ethnoidal, and Sphenoidal surfaces.

With regard to your dissection, you must sit by your part, and carefully trace each muscle and each important artery and nerve. You must be content with no slovenly performances, but endeavour to acquire an artistic skill; for just in proportion as you allow yourselves to fall into habits of carelessness, slovenly dissection, habits of inattention at lecture, habits of loose reading and still looser observation of the human body, so in the same degree do you run the risk of indulging in similar habits in the application of your medical and surgical knowledge to the patients at the hospital and in private practice. This is the answer to those who exclaim, "Oh, what's the use of cleaning this muscle, and what's the use of tracing this nerve. It won't help me in practice—it's of no consequence. They'll never ask that at the College." All these positions of yours might be right, and you might pass your examinations, and go into practice, and make yourselves agreeable to your patients as you ought to do, and do a great deal of business as represented by the account-books; but depend upon it it would make all the difference to you in the enjoyment of your profession, in your inner mental satisfaction, and in your appreciation of scientific labour, whether you have endeavoured to do that which your hand findeth to do with your might, and endeavoured to excel in what you have undertaken, or have been content with a minimum of attention, a minimum of work, a minimum of observation, and a minimum of examination of the cases in the hospital. For my own part, I dislike minimums. It is necessary to fix a minimum for examinations, but no man ought to aim deliberately—except under peculiar circumstances—at the attainment of a minimum. As Dr. Down observed in his introductory lecture, you should aim high. You may not always succeed, but you will have deserved success. If you aim at the minimum fixed by the College, I will not say that I hope you may be plucked, for, for the credit of the school, I might wish you to succeed; but I will say, at least, that you will not deserve to pass. And if I were to aid and abet any of you in this method of casting overboard everything that is not necessary for your examinations—if I were to make innocent Jonahs of some of the most interesting facts of anatomy—if I were to set before myself in this theatre as the great ideal of a professor's perfection "what they want at the College"—I should indeed be unworthy to occupy this chair. No, gentlemen, we will make special provision for preparing you for your examinations by holding classes for that purpose; but we will not in cold blood degrade any science by doling it out in the fragmentary and mutilated form which satisfies a corporate body which still stands greatly in need of reform. We will ask ourselves before lecturing on any subject how we can best teach it to you. We will enquire how we can best lay the foundations on which you may rear your medical and surgical knowledge. We will endeavour to condense and to generalise, and to avoid wearying you with details which may be more advantageously learnt at home from your text books; but we will set before ourselves no other principle than the relation of anatomy to the healing art. And if I, for my own part, could present anatomy to you in this relation according to the standard which my mind conceives, I should have little fear of any lack on your part of interest and attention. Never would there be a whisper heard of anatomy being dry, and of nothing being learnt at lecture. Such teachers of anatomy *have* existed and may exist again. Hear what Arnott says of Sir Charles Bell:—"In the lecture-room he was almost without a rival. His views were nearly always solid and always ingenious, while his manner and language enchained the attention of his audience. Dull indeed must have been the student who would have slumbered while Charles Bell was in the professorial chair. In his hands dry bones lived again, imagination investing them with the textures which had once clothed them. A muscle was no longer a mere bundle of fibres, arising here, inserted there; it was a guide to some important operation for the surgeon's knife, or kindling with some hidden fire betrayed by the anatomy of its expression the emotions which lurked within; and the flaccid artery on the table spouted forth its crimson stream, and demanded the arresting hand of the skilful surgeon, or threatened death as the alternative. In short, Sir C. Bell made his pupils think; and interesting as anatomy is as a branch of natural history, he taught them to value it most as a guide to the healing art."* The relation which a subject bears to the healing art is the true standard of medical teaching—the proper standard for examining boards to set before themselves in the demands which they make on medical students. If this relation were more clearly perceived and more thoroughly adhered to in the instruction imparted at our schools, and in the requirements of examining boards, a great deal of inappropriate matter would be removed from the curriculum; a great deal of interesting, important, and neglected matter would be incorporated in it; and a great deal of interest added to the study for the medical profession. This relation is the light by which I shall choose or reject anatomical details. Not seldom do I hear the opinion expressed that students should not be obliged to go deeply into anatomy, and should be relieved from learning minute anatomy. This opinion appears to me to be based partly on truth and partly on error. The erroneous element consists in the fact being disregarded that anatomical knowledge to be of any use as a foundation for medical and surgical knowledge, and as a basis for physiology and pathology, must be accurate and very often minute. The truthful element consists in the objection which the opinion raises against the introduction into medical teaching of details which merely burden and strain the memory without being really useful as a foundation for the superstructure to which I have referred. That anatomy must be sometimes minutely learnt is very obvious. How could you learn properly the diseases of the eye, or the diseases of the ear, or the diseases of the liver, without something more than a mere superficial knowledge of these organs? How can the diseases of the nervous system be understood without a considerable acquaintance with the course of the nerve fibres of the brain and spinal cord? A minute knowledge, or at least an accurate knowledge, of the various structural elements of an organ is necessary for building up a scientific medicine, and for the *presupposition* of disease on which Mr. Critchett dwelt in his introductory lecture. And, therefore, if you find me entering minutely into particular parts of the body, it will be because I consider such knowledge important.

A lecturer on anatomy must not be too ambitious. He must endeavour to confine his teaching to insisting on such anatomical facts as have a practical bearing, and such peculiarities as have an obvious use. He must endeavour at the same time to make his lectures something more than a mere repetition of that which the student will find in his anatomical text books. In this, my first full course, I cannot expect to be entirely successful. Ninety to a hundred lectures have to be given, and I am not a professor with a thousand a-year, and nothing to do besides lecturing but to spend the salary. I shall do what I can to be useful to you, and after Christmas shall commence my usual course of examinations with special bearing on

---

* I must plead guilty here to the offence, so strongly stigmatised by Mr. G. H. Lewes, of quoting at second-hand. I have taken the passage about Sir C. Bell as it appears in Mapother's Carmichael Essay, and I am indebted to the same source for the knowledge of the fact alluded to previously, that Vesalius inculcated the duty of recognising the bones by touch.

"what they want at the College." This course, however, will not interfere with the plan which I have always adopted of questioning the class at lecture. Sometimes it is a good plan to lecture for part of the time and examine for the rest. Mr. Cristopher Heath, I believe, uniformly lectured at the Westminster Hospital for three-quarters of an hour and examined for the remaining quarter. Sometimes I may think it more beneficial to adopt the excellent plan of Professor Humphry, namely, tell the class what to read up, and then examine upon it with additions and illustrations. Sometimes I may make the lecture a running catechism. Sometimes I may give a long lecture, sometimes a short one. Being somewhat of an eclectic philosopher, I prefer varying the mode of instruction according to the nature of the subject. With regard to questioning, some students I know feel an objection to it; they are naturally sensitive, and afraid of making themselves laughing-stocks by incorrect answers. This feeling soon wears off, but under any circumstances I recommend those who are not certain of the right answer to a question to say they do not know. It is the simplest plan, and one which involves no necessary discredit; as no one is expected to know everything that is asked him. Should any gentleman object to being questioned, I should always abstain from questioning him if he assigned a good reason for the exemption. It is not an essential part of the catechetical plan to hurt the feelings of anyone. We are all friends here, and I hope to see that good understanding grow up between the new students and myself which I am happy to think already exists between the lecturer and the students of the second year. This good and friendly understanding between teachers and pupils is the best preservative of order, without which no school can hope to flourish. "Order is heaven's first law," and we must look to the students to assist us in maintaining it. The reputation of a school does not rest solely on the ability of its staff, it is in the hands of the students also; and no loyal son of his Alma Mater would willingly act in any manner which would discredit her. The time has been when the London Hospital did not stand so high in the scale as it now does. During the last two years it has been rising and increasing. The members of the staff have applied themselves earnestly to the good work of augmenting the educational advantages of the college and hospital. They are still endeavouring to obtain funds for founding additional scholarships, and to secure the co-operation of the house committee in their plan of enlarging the school building, so that we may have larger space for the display of museum specimens, and may give the students what has long been a desideratum—a comfortable and commodious reading-room in addition to the library at the hospital. If you cannot aid us in any material manner, you can aid us by your sympathy and preservation of order.

Above all, reverence the dead. In one of my lectures on the brain, last year, I had occasion to remark that reverence for the dead was a proof of high organisation. All great peoples have set a value on human life and paid respect to their dead. Even among inferior races this feeling is not absent. The Chinese, who are not in the first rank as a civilised and intellectual nation, attach primary importance to an honourable interment. Shall it be said that the Caucasian race is inferior to the Mongolian—that the common orders among the Chinese show an example to Englishmen studying for the profession of medicine? It is given to us to learn secrets which are unknown and impenetrable to the outer world. Shall we not estimate this privilege at its proper value? Some of you may have seen a painting of Vesalius about to examine a dead body. The corpse lies upon the table, stiff and stark. On the one side stand two or three of the disciples of Vesalius, on the other Vesalius himself. His hand is raised as if about to use the knife. His countenance exhibits his emotions. It combines an expression of sacred thirst for knowledge, and a solemn awe at the dissolution of the mysterious union between body and spirit. He remembers that that corpse was once the temple of life—a temple never built by an earthly maker—and for a moment his hand is stayed. Gentlemen, let this reverence of a great anatomist be an example to you all.

Original Communications.

CASE OF EXFOLIATION OF THE ENTIRE CALVARIUM AFTER A BURN, WITH RECOVERY OF THE PATIENT.[1]

By Richard J. Kinkead, A.B., L.R.C.S.I., Tuam.

A woman named Margaret Sweeny, 70 years of age, called on me at my house on the 10th of September, 1868, and requested me to examine her head, which had been burned. On removing the cloths, &c., from her head, I found that the bones were exposed and quite dry, resembling the skulls we sometimes find in an old churchyard, a portion of dead dried scalp being left island-like at the posterior part of the right parietal bone.

There was a ring of large flabby granulations surrounding the denuded portion of bones, which were portions of the frontal and both parietals. The granulations exuded healthy-looking pus in considerable quantities, bled freely on being touched or on removing the dressings. They exactly resembled in appearance the granulation met with at the orifices of the fistulæ in connection with diseased or dead bone. The bone felt quite warm to the touch. There was also a fracture of right parietal bone. The aspect of the patient was anæmic; pulse feeble, but regular; tongue dry, red, and glazed along the centre; bowels inclined to be costive.

History.—She stated that she enjoyed good health till about ten years ago, when she was seized with epileptic fits, which, to use her own words, returned about "three times a quarter." She was always temperate. About three months ago (June, 1868), when alone in the house, she fell into the fire during a fit, striking her head against the "hob" as she fell. She did not apply to any medical man until she came to me, and dressed the wound for three months herself. At last, frightened by the quantity of discharge and the length of time the wound remained unhealed, she sought for medical advice. At no time from the date of her accident did she suffer from any head symptoms, not even from a headache; the only thing that annoyed her was the great discharge and the offensive smell of the pus.

She was ordered dilute chloride of lime and quinæ sulph., gr. j.; ext. taraxaci, gr. ij.; pil. rhei, gr. iij.; ft. pil., bis in die. She was given good nourishment; total abstinence from all stimulants; to be out as much as possible in the open air when the weather was fine; to avoid cold, and to keep the bowels open every day; and, more particularly, to avoid straining at stool.

Sept. 17th.—Going on well; tongue clean and more moist; pulse slow, but fuller; bowels regular; less smell from discharge.

24th.—Skull partly separated at front and at right side. Pulsation to be seen at line of separation; discharge not so great from left side and posteriorly. General health good.

31st.—Process of separation going on. Health good; some slight neuralgic pains in right eye and temple.

Oct. 8th.—Skull nearly separated; feels as if top of head would come off when she coughs. Pulse fast; face anæmic; neuralgic pains bad; stomach irritable. Ordered dilute nitric acid and bark.

The process of separation went on gradually till the 10th of November, when the head, being washed, the dead portion of bone slipped off into the basin.

I saw the patient about four hours after this occurrence.

---

[1] Read before the Surgical Society of Ireland on Friday, December 11th, 1868.

She was quite cheerful, and said she felt better than before it came off. The dura-mater was covered with fluid healthy granulations; pulsation of brain not discoverable; only slight traces of the convolution to be seen. The surface was *quite flat*, as if the top of the head had been sliced off with a knife.

Since November 28th she is going on well, the ulcerated surface gradually healing from sides, secreting laudable pus, and only requiring simple dressings and the occasional application of unguent. nit. to repress the exuberant granulation.

There are several points of interest about this case, the most remarkable of which is the total absence from first to last of any cerebral mischief, as shown by symptoms at least. No headache; no confusion of thought; no paralysis; no affection of vision, or hearing, taste, smell, or touch. The woman having been subject to fits for ten years, coming on regularly once a month, the fits commencing, according to her own account, many years since she ceased to be unwell. No trace of organic disease of any organ, and the total cessation of the fits since the accident. The flat surface presented, after the calvarium came off, showed that, in this case at least, the brain did not fill the skull, which was not peculiarly flat. There being no effect for good or evil produced by the atmospheric pressure on the surface of the brain, helps to disprove Kellie's notion, "that as atmospheric did not bear upon the cerebral circulation, it could never vary."

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Dr. Ogle's Cases of Abdominal Tumours.

(Continued.)

Case XL.—*Very large abdominal tumour in the iliac region, which proved to be owing to hæmorrhage from ulceration of the aorta.*

James G., æt. 30, an intemperate house painter, was admitted June 1, 1859, having been ill for six months with pain in the loins and left hip, increased by stooping. There was no pain on passing water, but he complained of inability to empty the bladder. Four years before admission he had had rheumatism, but not since. For three months he had had pain in the left hypochondrium, but had been at work up to May the 24th. His complexion was sallow, and he was weak, with a cold skin and furred tongue, and loss of appetite. The pulse was 120, and very weak, and no pulse was felt in the left wrist. He had had but little sleep of late. On the day after admission, a large tumour was found, extending from the diaphragm above, to a line joining at right angles the anterior superior spine of the pelvis below, and bounded by the median line of the body on the right. It was smooth, solid, and hard to the touch, and pulsated visibly. No bruit was heard. Urine was scanty, and contained much lithic acid, but no albumen. The whole, but especially the lower part, of the tumour was tender, and the superficial veins were turgid; some observers suspected that the tumour was an enlarged spleen. The blood was found to contain an unusual amount of white corpuscles. Enemata of morphia gave great relief to pain, &c.; he took iodide of potash and bark. At 9 P.M. of the 4th of June he had been to stool; he fainted whilst getting into bed, and died in about a quarter of an hour.

Post-mortem examination.—The thoracic organs were quite healthy, excepting that the heart was flabby.

On opening the abdominal cavity, a quantity of blood escaped. The liver was healthy; the spleen was smaller than usual, and pushed upwards. A large tumour was found behind the peritoneum occupying the entire left of the abdomen, formed by a large clot of blood, firmer in some parts than others, but not decolorised or laminated in any part. The peritoneum was tightly stretched over the mass, and it could not be found where the blood had made its way into the peritoneal cavity.

The abdominal aorta was pervious throughout, and lay on the right side of the coagulum. The anterior surfaces of the two last dorsal and two upper lumbar vertebræ were very carious, and opposite to these diseased vertebræ there was an ulcerated opening in the coats of the aorta about as large as a silver penny, around which the coats of the vessel were thickened and reddened. From the healthy state of the rest of the vessel, and from the situation of this opening, corresponding exactly to the opening of two of the lumbar arteries out of the aorta, it was conjectured that the source of the hæmorrhage was the coagulum, and the pancreas and descending colon adherent to the implication in the disease of the spine of one of these small vessels at its juncture with the aorta. The left kidney was embedded in clot. The kidneys were healthy.

The fibro-cartilaginous discs between the diseased vertebræ were natural.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

MEATH HOSPITAL.

RUPTURE OF THE FEMALE BLADDER—DEATH.

(Under the care of Mr. Collis.)

Julia G., æt. 26 years, a married woman, and the mother of six children, was admitted into the Meath Hospital December 10th, at 12 noon. She was a woman of intemperate habits; and on the night of December 7th had retired to bed under the influence of drink. She got up to pass water, but failed to do so, and in endeavouring to return to her bed she fell over the wooden foot-board and fainted; she was then lifted into bed, where she remained until morning, when she complained of pain in the hypogastric region, and inability to pass urine. She said that she felt as if "something had given way inside her;" and upon a renewed effort she passed a small quantity of water mixed with blood.

On admission to hospital, on the third day after the accident, she complained of pain and tenderness on pressure in the right side of the hypogastric region; her abdomen was much distended and tympanitic; and on introducing a large male gum-elastic catheter, about a pint of urine mixed with blood and clots was drawn off, about the same quantity trickling away afterwards.

A warm poultice was applied to her abdomen, and an enema containing castor-oil and tincture of opium was administered, as her bowels had not been moved for several days.

She then expressed herself much relieved, as the enema operated well, and removed a quantity of flatus; and about two hours afterwards she voluntarily passed several ounces of urine mixed with blood. She remained much in the same condition until 5 o'clock a.m., December 11th, when she commenced to vomit considerable quantities of dark-coloured fluid, and complained of great pain in the hypogastric region. She again passed a few ounces of urine.

The following mixture was ordered:—

℞ Acidi hydrocyanici dil. ♏xij.
Liquoris bismuthi, fl. drs. ij.
Spiritus chloroformi, fl. drs. jss.
Aquæ ad., fl. oz. vj.

Two tablespoonfuls every second hour.

Six leeches were applied over the hypogastric region, and a large warm poultice was afterwards placed in the same situation, and she was administered two grains of powdered opium.

Dec. 11th, 9 a.m.—Patient stated that she was much relieved, but lay in the attitude of peritonitis; the vomiting had nearly ceased, and the pain was diminished. She was ordered a suppository, containing half a grain of morphia, every fourth, and a tablespoonful of brandy in a cup of milk, every second hour. At 3 o'clock p.m., however, she suddenly began to sink, and at 5 p.m. she expired.

A *post-mortem* examination was made on the following day, when the pelvic portion of the peritoneum was found to be inflamed, and to contain about one quart of dark-coloured serum, but was free from any appearance of plastic effusion. The peritoneum was not ruptured, but on passing the finger over the anterior surface of the bladder, a cavity was found containing fluid of a urinous odour; and beneath this, where the viscus is uncovered by serous membrane, a large transverse rent was discovered. There was some effusion into the cellular tissue surrounding the bladder, but none into the labia. The coats of the bladder appeared to be quite healthy, but no attempt at reparative action had been set up.

The rarity of rupture of the bladder in the female renders this case of much interest; indeed, Mr. Collis believes it to be unique, the only accident at all resembling it which he is aware of, being one recorded by Professor R. W. Smith, the account of which may be found in the *Dublin Journal of Medical Science*, vol. xxv., page 176. The cases resemble each other, inasmuch as they were both caused by direct violence applied to the front of the abdomen, but differ in the situation of the rupture, in Prof. Smith's case the rent being in the posterior superior part of the bladder, while in Mr. Collis's it was situated anteriorly where the bladder is uncovered by peritoneum.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

December 8th, 1868.

Mr. W. P. Bain read a paper

ON A NEW AND SIMPLE METHOD OF INDUCING ARTIFICIAL RESPIRATION IN CASES OF ASPHYXIA FROM DROWNING, STRANGULATION, CHLOROFORM, POISONOUS GASES, &C.

Having spoken of the various plans that have hitherto been tried, and given full praise to both Dr. Marshall Hall and Dr. Silvester, and noticed the defects of their methods, he introduced a plan not known in this country, the invention of Pacini. It consists of placing a patient on his back on a table or bed, the operator having his abdomen against the head of the patient, placing his hands in the axillæ on the dorsal aspect, and then pulling the shoulders towards him with an upward movement at the same time. The shoulders are next relaxed, then the former movement is repeated, and so on alternately. In many cases operated on by this method the air makes a loud noise when it passes the larynx, as in snoring.

Dr. Bain was so impressed with the value of this plan that he determined to make experiments on it, as suggested to him by its inventor. In doing so he soon discovered two modes considerably superior, and throwing also somewhat in the shade the labours of Marshall Hall and Silvester. In experimenting on the dead subject he employed an india-rubber tube, one end of which was tied in the trachea, and the other communicated with a small spirometer, upon the principle of Hutchinson's, so that the passage of air to and fro the lungs could be easily observed by means of a scale showing cubic inches. He found that the simple process of raising the upper part of the thorax from the table by taking hold of the arms caused a considerable influx of air, varying with the angle that the arms made with the body. For instance: by raising the body by the arms at an angle of 45 degrees (towards the face) the air inspired would amount to 20 cubic inches. If the body were lifted by the arms in a vertical direction, the amount would be 15 cubic inches, and if pulled up by the arms at an angle of 45 degrees (towards the feet), the amount would be about 10 cubic inches. But by the first of these modes a quantity of air considerably greater than by Hall's or Silvester's plan was generally obtained.

Dr. Bain's best and simplest plan is founded upon Silvester's and Pacini's conjoined. Placing his fingers in the axillæ in their front aspect, with his thumbs over the outer ends of the clavicles he simply draws the shoulder towards him. On relaxing his hold, the shoulders and chest return to their former position, and the act is repeated. Thus only one movement has to be effected instead of three, and the fatigue of having to bear the weight of the patient's arms, as required by Dr. Silvester's method, is avoided. This is all accomplished in a more rapid manner than any other plan. The quantity of air inspired at each movement by this plan is about 30 to Dr. Silvester's 20, and as the operation can be conducted with much greater rapidity, the author considers that at least twice the quantity of air can be inspired by this mode than by any other yet known; and he expresses a wish that a subject which is of such practical importance should be further investigated.

Mr. Bowles said that Dr. Bain's description of the Marshall Hall method, was incomplete, and that, if so practised, it had not been fairly tried. Pressure on the spine when the patient was rolled into the prone position was an important element. In cases of drowning, the first thing to be done was to get rid of the water from the lungs, it having been proved by the experiments instituted by the Committee of the Society, that this water was the chief source of danger to life. The presence of water in the lungs of drowned persons had also been shown by Casper. In the case of a patient brought to St. George's Hospital, and who died there shortly after arrival, water was found in the lungs churned into foam by the air introduced by the diligent practice of Silvester's method. We do not usually find water in the mouth, because it escapes easily, even from the larger bronchi, during the transport of the patient; but it does not escape easily from the smaller tubes, and in them it may be soon churned into froth. There is no difficulty in the introduction of air into the chest, but the introduction of air is useless while the patient is in the supine position, and while water is retained. A person with suspended animation requires but little air, and any method will introduce enough. The important question is, By what method can the water best be got rid of?

Dr. Silvester remarked that injury to the parts entering into and surrounding the shoulder-joints, might occur in Dr. Bain's method. He thought it similar in principle to his own, but that it was safer to act upon the chest through the arms. He objected to frequency of artificial movement; if the movements were too frequent, air would not pass below the bronchi, as might be proved by the use of the stethoscope. Dr. Bain has been less successful with his (Dr. Silvester's) method than the Committee of the Society; he would himself undertake to introduce into the chest by means of it, not thirty or forty but sixty cubic inches of air. He was desirous to get rid of water when it was present, but did not believe that it usually entered the lungs. He had failed to introduce it even by injection; and, if it did enter, it could not be got out again either by the Marshall Hall method, or by position. The Marshall Hall method was not new, but had been used and reported upon by the Royal Humane Society a century ago. It was open to grave objections, and often seriously injured the patient.

Dr. Headlam Greenhow said Dr. Bain's method was the best, tested by the quantity of air introduced. He believed that water was distinctly inhaled into the lungs in drowning, when people fell into the water in a state of consciousness, and made efforts to breathe. Water was not found in the lungs at *post-mortem* examinations unless they were made soon after death.

Dr. Peacock suggested that Dr. Bain's and other methods should be referred to a committee for investigation.

Mr. Clover referred to the great importance of being acquainted with the best means of maintaining respiration in cases of suspended animation from anæsthetics; and expressed a belief that more of such cases than usual might possibly occur in consequence of the free use now being made of nitrous oxide. He thought, in chloroform cases, that the first thing to do was to expel the chloroform-laden air from the chest, and then to maintain artificial respiration. He found that respiration always stopped before the action of the heart; and he had himself used Silvester's method with great advantage. He had seen resuscitation after forty seconds of suspended breathing. He recalled to the Society Dr. Marcet's apparatus for supplying air to the lungs.

Mr. Carter confirmed Dr. Silvester's statement about the antiquity of the Marshall Hall method, which had been used by midwives in Dr. Marshall Hall's native county from time immemorial as a means of recovering new-born infants apparently dead. Dr. Marshall Hall stood in the same sort of relation to the method that Jenner did to vaccination. He thought that the best means of maintaining artificial respiration was the application of a Faradaic current to the phrenic nerves, where they pass over the scaleni muscles, according to the method described by Ziemssen. By this means patients apparently dead from chloroform, and from the inhalation of carbonic acid and of coal gas, had been restored to life; and recently Pernice had applied the same means successfully to new-born children, who could not be made to breathe in the ordinary way. One of the convenient galvanic batteries now made by Stöhrer and others should always be at hand when chloroform was being administered, or at places where deaths by drowning were liable to occur.

Dr. Barnes confirmed the remarks of previous speakers with regard to the inconvenience or danger of the Marshall Hall method as applied to infants.

Mr. Jones said that several years' experience as house-surgeon at St. George's Hospital led him to prefer the method of artificial respiration by intermittent pressure upon the parietes of the chest and abdomen. The difficulties of the Marshall Hall method were very great, especially with heavy or bulky patients.

Dr. Bain in his reply said, his only object had been to find the simplest and easiest method of introducing air into the lungs. He could not explain the better results obtained by his method, unless (the idea had only occurred to him during the debate), they might be due to the circumstance that the thorax was elevated directly, through the clavicles and sternum, instead of indirectly through the latissimi muscles.

DUBLIN PATHOLOGICAL SOCIETY.

January 9th, 1869.

Dr. McClintock in the Chair.

Dr. Jennings exhibited an interesting specimen of "Pericarditis," and in doing so expressed his regret that he was not in a position to lay before the Society the full particulars, *ab initio*, of a case so replete with interest, and which presented to the pathologist phenomena so unusual in extent.

The patient from whom it had been obtained—a man aged 42 years, of stout and muscular habits, and who had been admitted into the South Dublin Union on the 24th December, 1868—was suddenly seized with extreme collapse on the evening of the 27th; and when visited by the resident pupil was found lying on his back comatose, with livid and swollen features, and almost imperceptible pulse. From this condition he was roused, and then only partially and for the moment, with much difficulty, replying to questions with slow and indistinct mutterings, and instantly relapsing into his former state of stupor.

Under general and prolonged stimulation the heat of surface was somewhat improved, though no other change could be detected in his condition until the following morning, when it was remarked that his insensibility was slightly less profound, and that he answered more promptly and distinctly. On physical examination extreme dulness was found to exist on both sides of the chest except on the upper and anterior part of the right, where coarse and puerile respiration was audible. No heart sounds could be anywhere detected, nor could any pulse be felt at either wrist. His face was still congested and discoloured.

From this time he gradually sank till his death, which took place the following day at three o'clock.

On a *post-mortem* examination, for which he was indebted to his friend, Dr. Purser, who had kindly conducted it, the right pleural cavity was found nearly two-thirds full of serum, and the upper lobe of the right lung presented a puckered appearance, being also solidified throughout almost its entire extent. On section it was seen to be of a greenish grey colour, thickly studded with tubercle, and containing a few small cavities. The middle lobe also contained a few tubercles, but was generally crepitant. The upper portion of the lower lobe was likewise solidified and tubercular, the lower being still more solid and fleshy, and containing several patches of apoplectic effusion. The left pleura was intimately adherent throughout its entire extent, and the upper lobe of this lung was extremely solid and tubercular, as also the lower, which in the rest of its extent was, however, more or less crepitant. The trachea contained much tough mucus. The bronchial glands were enlarged and tubercular. The pericardium was closely adherent to the surrounding parts, the visceral and parietal layers being separated by a layer of lymph, in some places nearly half an inch in thickness; this was in parts soft and fleshy, and in parts closely adherent to the proper pericardium, which itself was very much thickened. The effusion of lymph was exceedingly abundant about the base of the heart, completely concealing the origin of the vessels and the auricular appendices. On the right side the valves were healthy, but the muscular structure of the right ventricle was somewhat thickened, and had in parts, especially at the apex, apparently undergone fatty degeneration. The pulmonary artery was healthy.

The walls of the left ventricle were soft and of yellowish brown colour, and apparently fatty. Both the mitral and aortic valves were healthy. The apparent enlargement of the heart was due to the deposit of lymph on its surface.

The adventitious coat of the aorta was seen to be studded with numerous small extravasations, and the vessel when opened presented an extremely advanced state of atheromatous degeneration, the inner coat being thickened, wrinkled, and covered with spots of atheroma, some of which had ulcerated, and others formed broad bony plates.

Dr. Jennings remarked that the case which he had just recorded presented many features of no ordinary interest, not merely as an instance of sudden death, which many might pardonably have, without examination, attributed to central agency, but also from the strange latency of all symptoms of suffering during life—a fact which was rendered still more inexplicable when it was borne in mind that these various morbid changes, which had reached so extraordinary a degree of development as to seem incompatible with the continuance of life, had undoubtedly been produced by repeated attacks of acute and intense inflammatory action; yet, nevertheless, neither had the patient made any complaint while under his observation until immediately before his death, nor, so far as he had been able to ascertain, had he been at any time under medical treatment.

December 12th.

Mr. Collis exhibited a circular piece of bone which had come away by exfoliation from a trephine wound, which he had made in the centre of the tibia of a young gentleman who had contracted syphilis five or six years previously. Since then he had been abroad, and had suffered from periostitis engaging the greater part of the bone; besides this, however, he complained of a very severe pain in the tibia, which he described as of a bursting character. He had been under the care of several medical men both in this country and in England, and said that he had taken large quantities of iodide of potassium. The entire length of the bone was thickened. Dr. Collis came to the conclusion that it would be necessary to trephine the tibia. He accordingly proposed it to him, and he at once assented to the operation being performed. On proceeding to operate he found that not only was the bone of double its ordinary thickness, but it was of such extreme density that he broke two trephines before he got to the centre of the medullary canal; and he would not have succeeded but that he had by him Mr. Samuel Smith's augur, which enabled the operator, once he got into the bone, to go through it with great rapidity. The patient said that from the moment the cavity was opened the peculiar bursting sensation disappeared.

This patient was three or four months under his care. He would not allow the wound in the bone to heal, until by degrees the inflammatory material had drained away, and until all pain in the limb had disappeared. He was now able to walk about, and the wound was completely cicatrised over. This case was especially instructive, as it proved that all cases of this kind should be examined with great caution; for with a man who had had syphilis, and complained of these pains, it might naturally be supposed that there was nothing but periostitis the matter.

The next case to which Mr. Collis directed the attention of the Society was one of cancer of the penis, which he had removed during the present week. It had as usual engaged a large portion of the prepuce, and somewhat involved the glans. It commenced ten years ago as a fissure of the prepuce, which had been slit up, not through the fissure, but at some distance from it; this, however, had not checked the disease. One peculiarity of the case was, that the age of the patient was only 35, though he looked at least ten years older, owing to the whiteness of his hair and the pallor of his countenance, and in consequence the disease must have originated when he was 25 years of age. It was very rare at this early period of life to find cancerous disease, whether epithelial or scirrhus, in this locality. There was no appearance of engorgement of the glands in the groin. Although the disease had extended but a short way up the corpus spongiosum, he removed about an inch of the organ.

Mr. COLLIS then exhibited a specimen of ruptured bladder in the female, which he considered quite unique. A full account will be published amongst our Hospital Reports.

Dr. LITTLE exhibited the brain of a man aged 32, which presented the following morbid appearances:—Over the frontal convolution on the left side the arachnoid sac wos completely obliterated, and the dura mater inseparably united to the grey matter beneath, as far back as the fissure of Rolando, except at one spot somewhat above and behind Broca's region, where a firm well-defined tumour, growing from the under surface of that membrane, and the size of a filbert, had made for itself a bed in the brain structure. The patient was brought to the Adelaide Hospital in October by his wife.

He had a vacant expression of countenance, and was feeble on his limbs. He understood what was said to him, but had considerable difficulty in finding words for reply. He had been seven years in Bengal, but when asked in what stations he had been he could only remember Calcutta. He could not tell the name of the street in which he lived. He had also difficulty of articulation, speaking like a person with an acute tonsillitis.

On examining him he found that he had an induration on the prepuce, and also found on his legs several of those scars which they were accustomed to associate with syphilitic eruptions. From his wife he learned that he went to India as a soldier in 1858, came home in 1865, and married in 1866; his wife miscarried when three months pregnant on the first occasion, and when seven months on the second occasion. Since his death she has given birth to a living healthy child. For the first year after his marriage he had severe pains, which were worse at night, but otherwise he was in good health till the summer of 1867, when he became cross and irritable; and in October he was suddenly seized one evening with a violent pain in his head, of which he complained incessantly till July, 1868, when his wife noticed his becoming silly, and in October of the present year he had a succession of epileptiform fits. These were succeeded by difficulty of articulation, difficulty of swallowing, and great feebleness of the limbs.

In that condition he came into hospital. He lived a few weeks, passed his motions under him, became more feeble every day, and so died. The only morbid appearances were those he had already described. They corresponded with those described by Dr. Wilks in connection with syphilitic disease of the brain, the whole subject of which was so ably dealt with by Dr. Barton in his recently published work.

MEDICAL BENEVOLENT FUND.

THE annual general meeting of this charity was held on Tuesday, January 12th, Dr. Lloyd Birkett being in the chair. In the Report of the Committee it was stated that one hundred and six cases had been relieved during the year. The total amount thus expended being £855.

In several instances grants from the fund had been made conditional on a certain additional sum being raised by the friends of the applicant with excellent results.

The number of annuitants at present is 27, and it is hoped that the Committee will soon be able to add to these as the candidates are numerous and many of them in most distressed circumstances.

The Committee and officers for the ensuing year were elected, and the thanks of the meeting were given to Dr. Broadbent, who resigned, after holding the office of honorary secretary since 1864.

The successor appointed to the somewhat arduous duties was Stamford Felce, Esq.

In conclusion, a vote of thanks to the medical press was moved by J. H. Hills, Esq., and unanimously carried. Every disposition had been shown by the editors of the various journals to aid in bringing the charity before the profession, and the principles on which it is conducted cannot fail to recommend it when they are known.

All the work is done gratuitously by members of the Profession, and those who require the aid of the Fund have only to show that they are really in need, and that their position is the result of misfortune, and not of misconduct, and assistance is at once given without canvassing.

◆

Literature.

THE class of work to which this book belongs[1] is one which has only made its appearance during the past few years. Our fathers had many more difficulties to contend with in the study of medicine and surgery than we have; their educational works were limited in number, and such a thing as a text-book, or short compendium of any branch of medical science or surgical art, was almost unknown. We now find the tendencies of authorship changing in this respect, and many small outline works issuing from the press. The alteration is in part due to the fact, that the more any science progresses, the more arbitrary it becomes, and as its limits define themselves more clearly, its disciples can more readily express their ideas in a concise form; also, perhaps, in some degree to the demands for an improved system of medical education, and the efforts made to meet them. Mr. Bell's book is one which we can safely recommend to the attention of those for whom it has been written—students and junior practitioners—and particularly to gentlemen competing for the Military or Naval Medical Services. It endeavours in no way to assume the place of a "system" of surgery, or to deal with the general considerations of operation, such as may be found fully expressed in the larger works upon the Science and Art. It purports to be no more than it really is—a very concise and clear account of the principal surgical operations, without any attempt at historical completeness or particular detail.

There are, perhaps, a few points in which we think the book is faulty or imperfect to some slight degree; for instance, we hardly understand why in such a work no mention is made of acupressure, more particularly when it is written by one who confesses to "northern proclivities," and who is a fellow-countryman of Sir James Simpson; nor can we agree with the author in considering deligation of the anonyma an operation "by no means so difficult as might be expected." In this, perhaps, most surgeons will hardly coincide with him, for even when the vessel is in a normal situation, its ligature is difficult enough, to say nothing of the alteration of its position and relations which may result from disease.

◆

CESAREAN SECTION PRODUCED BY CAUSTIC.

A SINGULAR case is related in the *Philadelphia Medical and Surgical Reporter*, in which Vienna paste was substituted for the knife in opening the abdominal parietes. It occurred in the practice of a French surgeon. The patient in the sixth month of pregnancy, was found to have the fœtus developed in the right Fallopian tube. It was apparently dead. Her health was failing fast, and there was reason to fear that the operation with the knife would prove fatal. Under these circumstances, a strip of adhesive plaster with a slit four inches long and a half an inch wide was secured over the prominent portion of the tumour, and a thin coating of Vienna paste applied along the fissure for three minutes. The pain was violent. In two days more the caustic had eaten through the oblique muscles down to the fascia and now it was again applied for five minutes, with trifling pain. On the removal of the dressing the next day, an opening through the abdominal walls was discovered, which was enlarged by the finger, the parts having been disintegrated by the caustic. Through the opening by careful manipulation and dismemberment, a fœtus of normal size was abstracted. The cavity being cleansed, an examination showed that an agglutinization of the parts had been effected, the inflammation being local and not involving the peritoneum. The patient was calm, without pain or distress, and the pulse normal. In a few days more, when the edges of the opening were clean and healthy, adhesive strips were applied. She improved rapidly, and sat up in bed in twelve days after the removal of the fœtus. Two weeks after this, when the wound was nearly closed, the cholera which invaded the hospital, carried her off.

PAUPERISM.

THIS great evil of our large cities continues to occupy public attention, and the discussions lately opened will be followed by others of equal interest.

The facts accumulated, and that have already been recited in forcible papers by Drs. Hawksley, Stallard, and others, are likely to produce an impression on the public mind ; and without necessarily adopting their conclusions, we can heartily rejoice that their statements have been so widely disseminated. To hear that pauperism in the metropolis alone has nearly doubled in the last decade is certainly startling, and other figures have been published which give still greater cause for anxiety. The expenditure of course increases in a still more rapid ratio, and the striking point is that this expenditure seems to reveal that the increase of pauperism is due, not to the disabled paupers, but to the much larger class who get indiscriminate out-door relief. This shows that while our workhouses have been scenes to make a civilised country blush, more than enough money has been contributed by ratepayers to render them all they should be, and this money has been squandered in bestowing useless alms by way of assisting other poor persons. Dr. Stallard relates a story about Whitechapel which is a disgrace to the Board of Guardians. The number of persons in that parish who claim assistance from the Poor-law medical officer had increased from 5,000 to 20,000. Dr. Stallard says that the relieving officer has been known to cry out to the crowd of paupers, "Who wants an order for the doctor?" and that people took the orders, well or not, because through the doctor they had a chance of more liberal relief. Of those who took these orders nearly half were improper objects. Now we defy any board to institute a more disgraceful practice than this. For the doctor to be thus turned into a relieving officer, and overburdened with work he never contracted to fulfil, is a fraud upon him, besides which it encourages a spirit of pauperism in the population which a wiser course would tend to remove. We protest against such a thing as an iniquity degrading alike to every one concerned in it, and of the utmost danger to the community.

What is the remedy for this state of things? That is a question on which great difference of opinion will prevail. It has been proposed by some members of our profession to institute a scheme of public employment for the able-bodied poor. This we are convinced this country, with the lamentable examples of its Continental neighbours before it, will never consent to. It has been argued that starvation is the natural stimulus to work for the able-bodied but idle. Dr. Stallard, with a certain degree of force, replies that in a country where so much indiscriminate charity exists, starvation is by no means a necessary consequence of idleness; that if it continue for any length of time physical incapacity results; and that want of work with consequent destitution is often beyond the labourer's control. Plausible, however, as this reply seems, it is not enough, nor does it by any means show that the question has been sufficiently investigated. It is easy enough to devise a grand scheme of public employment, but we imagine it is altogether a different thing to prevent it from becoming a danger to the State. It is a fact that such plans have always undermined the securities of society, and not unfrequently brought infinitely greater evils than they can be supposed likely to restrain.

It is recognised, we admit, by the advocates of public employment, that such work must be strictly limited; but once bring the scheme into operation and such limitation would, we fear, prove practically impossible. The philanthropists would maintain that the limit must enable a man to support his family in health, and the "right to work" to that extent once conceded, the State would become the only employer. Even those who earnestly support the proposed innovation would hesitate if they saw clearly that this must follow, and we think that our statesmen are not at all likely to omit to look along the vista set before them far enough to discern shapes of terror distinctly enough to deter them from entering on the path.

EDUCATIONAL REFORM, No. VII.

ALTHOUGH the arguments in favour of the possession by the Medical Council of an absolute authority in educational matters have not been exhausted, enough has been said to prove the expediency, and even the necessity, of the change. The results which this change would be likely to produce have been pointed out in our preceding articles, and constitute some of the strongest of the arguments in its favour. We are not so sanguine as to suppose that the profession will arrive at these results very expeditiously, for, if we are to judge by the past, progress will be effected by slow and painful steps. But still there seems to be an earnest spirit abroad which will not suffer the great questions at issue to be shirked or shelved. There is a tendency to greater union within our ranks. Organisations such as the Medical Teachers' Association and the Medico-Political Association have sprung into existence, and are not inclined to sink into cyphers. The latter, indeed, appears at present to be in a state of hybernation, but the former has been amending or rather altering its report. We cannot say that we are altogether satisfied with the alterations, nor can we think that medical students will be satisfied, or that the great body of the profession will be satisfied with the proposed curriculum. It is, however, a great point gained to have passed the report, defective as we think it in some important respects. We will not dwell now on what we think ought to be altered because we can incorporate our remarks with the discussion of the medical curriculum. Into this subject we are about to enter and propose almost immediately to turn our attention to the course of study and examinations which in our opinion should be undergone by those who are to enter the medical profession before the minimum qualification is conferred. We shall not minutely discuss the proper mode of teaching each individual subject, as that is a matter of detail which under our system would be thrown upon the schools to determine for themselves, but we shall treat each subject with a view of deciding upon the amount of knowledge which the student should acquire, and when and how he should be tested in that knowledge. These are points on which it is extremely desirable to collect the opinions of our professional brethren without delay, and we invite an exhaustive discussion of them. We are ourselves most anxious that the whole subject of educational reform in all its branches should be thoroughly ventilated before the next meeting of the Medical Council. At its last sitting Mr. Syme proposed and carried the motion, "That a committee be appointed to consider and report how the various subjects of medical education which have been deemed requisite by the Council may be taught with most advantage, in what order they should be studied, and how the examinations in them ought to be arranged." A committee was appointed, and drew up a letter requesting information on the points of inquiry, and signed by Mr. Syme, the chairman. A copy of this letter was said to have been forwarded to all the teachers in recognised medical schools, but it miscarried in our own case, and did not reach us. Subsequent advices recorded in the medical journals state that the committee has collected a large body of evidence. It will, of course, draw up a report for the next meeting of the Council, when an important debate may be expected.

Whether it will result in any practical conclusion beyond the ordinary "recommendations," or whether any definite plan of action for the future will be decided on, must be dependant to a great extent on the attitude assumed by the Profession. It is a matter of the greatest difficulty to obtain a clear and combined expression of professional opinion in the form which would authoritatively show what the general opinion really is, and beneficially influence the progress of legislation. There are the best of reasons for believing, and asserting, that the profession is thoroughly dissatisfied with the composition of the Council, and with many clauses in the Medical Act. They are beginning to see clearly that at the bottom of the great question of Educational, and therefore of Corporate Reform, lies reformation of the Council itself. Add to the Council representatives of the Profession, make it a thorough representative body, give it absolute authority to enforce uniformity on fair and honourable conditions to the corporations, make it the medium between Parliament and the Profession in regard to legislation affecting professional interests, and all the results for which medical men have been sighing and labouring would be obtained in a twentieth part of the time which they would otherwise occupy with the circumlocutory machinery now at work. Shall we ever effect our object by means of endless committees, endless reports, endless discussion of these reports, endless adoption of recommendations, endless visitations to see if the recommendations have been carried out by the nineteen corporations, endless discoveries that some of the licensing bodies refuse compliance, endless committees on the refusals and answers of the nonconforming and conforming Boards, endless recommendations throwing overboard former recommendations, which, like the demand for Greek, were premature; endless collection of material which, according to Dr. Paget, could only have been collected by a Royal Commission at the cost of thousands of pounds, but which no one ever looks at out of the precincts of the Council? We trow not. Why not make short work of the matter and at once agree among ourselves what amendments are required in the Medical Act of 1858, and then never cease to agitate until we have obtained our requests? Governments do not favour us, and are inclined to snub us, but if they will not "rise and give us the three loaves" we ask for because they are our friends, our "importunity" must extort them. What were the words, in 1867, of Dr. Alexander Wood at the Medical Council? "Those of us who were engaged in the struggle which resulted in that misshaped, misbegotten Bill which we have sat nearly ten years in trying to administer, know very well that even that wretched miserable Bill would not have been entertained unless year after year the various bodies represented at this table, and the Profession generally, had besieged the doors of the House of Commons until, at last, in self-defence, in order to get rid of our importunity, tney were obliged to pass the Bill. Our remedy is to resort to the same process again, laborious, difficult, and disagreeable as it may be. We are not delegates, but representatives from the different bodies; but I think that we have, perhaps, a little erred in not taking the bodies that we represent sufficiently along with us in our struggles for Medical Reform. You cannot take up a single number of a medical journal which refers to the Medical Council without seeing that we are taunted with not having done things that the present Medical Act renders it impossible for us to do. The utmost ignorance prevails among medical practitioners in regard to the powers which we possess under the Medical Act, and we are continually blamed for not exercising powers which the law has not given us. Now, let us throw ourselves back upon the bodies we represent, and the Profession generally, who feel the necessity for the reforms for which we have been contending, and let us before our next meeting stir them up to besiege Parliament for a proper measure that we may be able satisfactorily to administer." "Beautiful language!" as Mr. Joey Ladle observed. But what has come of it? Did Dr. Alexander Wood take any steps to put his views in force? There was no evidence that he had done so forthcoming last Session. Dr. Andrew Wood proposed that the Council should consider its constitution, and the question of the direct representation of the registered practitioner. Dr. Alexander Wood, though willing to go into committee in a general way, not only did not support Dr. Andrew Wood, but abstained from voting on his motion. Yet surely he must have been well aware that if there is one reform more than another in regard to which he could rely on the support of the Profession, it is the reform of the constitution of the Medical Council. But possibly Dr. Alexander Wood is not an advocate for an alteration in the constitution of the Council. If not, what is the grand scheme of reform which he had in his mind when he exhorted the Medical

Council to fall back on the Profession? Let him produce his plan, and let him state how he would propose to "stir up the Profession" in its support. He is bound down by his own words to do it, and we call upon him to redeem them without delay. He has a great opportunity; the opinion of the Profession is ripe, but the Profession is in want of a leader of ability and influence. A member of the General Medical Council, in Dr. Alexander Wood's position, might at least obtain a committee to collect professional opinion on the amendments required in the Medical Act, to draw up a draft Bill embodying all the practicable and desirable amendments, and then appeal to the Profession to ensure its passage. Nothing could possibly have been a more "lame and impotent" conclusion than the adoption of Mr. Syme's amendment last year, that it was inexpedient for the Medical Council, under existing circumstances, to take its constitution into consideration. The arguments used in favour of the amendment went merely to show that it was unlikely that an amendment of the Medical Act could be passed at an early date on account of the state of political parties and Irish Church discussions. But because no Bill embodying a reform of the Council could be carried this year, was precious time to be wasted and nothing at all done? Even supposing that the Council could not have succeeded in getting a Bill passed till 1870, was that a reason for deliberately wasting a year of the interim? Was it not rather a strong argument in favour of organizing the Profession for an united effort, for thorough inquiry, for collection of opinion, for digestion of material thus collected, and for maturing a plan of action? Unless the Medical Council assumes the lead of the Profession, becomes the "minister and interpreter" of professional opinion, the faithful reflex of the real wants and true aspirations of medical men, it will degenerate into a cumbrous engine for the production of wasted words and worthless work, at an annual cost of 4,000*l*., or 5,000*l*., a year. For such a sum the Profession looks for a fair equivalent. We do not underrate the good which the Council has achieved. It has been placed by the Legislature in a position of no mean difficulty, and up to the present time it has felt the necessity of proceeding "delicately." But it is very evident, from its mode of discarding Greek, and from other symptoms, that it has nearly come to the end of its tether, so far as further good can be expected to issue from "recommendations." It may be true, as Dr. Burrows said in his opening address in 1867, in regard to the "Visitation of Examinations," that "a more rigid, uniform, systematic plan might, in the first instance, have met with more opposition, might have given rise to heartburnings, and afforded less satisfactory results than have been obtained by the cautious, tentative, but more imperfect system which we have hitherto adopted." But the time has now arrived for a bolder policy. The members of the Council may possibly think, with Bacon in his "Essay on Boldness," "that boldness is a child of ignorance and baseness, far inferior to other parts." Bacon, however, as Whately observes in his Annotations, had "that over estimate of those who are prudent which is rather common. The failures, that is, the non-success of the over-cautious, cannot be distinctly traced. Such a man only misses the advantages, often very great, which boldness and free-speaking might have gained. He who always goes on foot will never meet with a fall from a horse, or be stopped on a journey by a restive horse; but he who rides, though exposed to these accidents, will, in the end, have accomplished more journeys than the other." We shall be glad to see the Medical Council on horseback,—provided it does not direct its horse's head towards the proverbial destination of beggars similarly situated.

SCOTLAND.

EDINBURGH.

The Medical Missionary Society was held on the 9th instant at St. Andrew's square, when a paper was read by Dr. Grainger Stewart on the "History of Medical Missions."

THE INFIRMARY AND THE MATERNITY HOSPITAL.

Sir J. Y. Simpson has written to the *Scotsman* on the subject of hospitals, particularly those of Edinburgh, and, from some introductory observations, he lays down four propositions:—1. About three times as many patients die after limb amputations in our large hospitals as die from the same operations in private and country practice. 2. Hospitals seem generally to be much more healthy when first built than after they become used for some years. 3. To reduce the death-rate from operations in our surgical hospitals, we should, perhaps, specially strive to assimilate the form and arrangements of these hospitals to the condition of patients in private and country practice when these operations are so much more successful. 4. If permanent stone and lime structures are raised, there should be many wards of reserve, so that every ward should be duly cleansed and fumigated every few months in turn.

The inference from these propositions he states as follows:—

"Hence, I believe, the larger the area over which our new hospital is spread, the safer and the better will it be for the patients. If retained in the present site I hope many acres of ground will be added to it behind, from the Pleasance side. If moved to Watson's Hospital grounds, I trust that, in addition to these grounds, those belonging to the Poorhouse will also be secured without fail. It is our duty to place the inmates in our hospitals under every possible means to avoid contagious diseases in either the wards or airing grounds, as well as to ensure and expedite their recovery by the best hygienic form of the buildings, I hold that a new Maternity Hospital should be built in connection with the new Medical Hospital. It should certainly not be large; should be built cheaply, and with temporary rooms and wards; and should be a structure, like the Lock, Fever, and Small-pox Hospitals, separated from the other hospital buildings."

GEORGE WATSON'S HOSPITAL.

A correspondent of the *Scotsman* of Thursday reminds the Merchant Company of the price they put upon their property in March, 1867, and observes:—"We have all heard of Midas with his *long* ears, at whose wonderful touch everything became gold. Have the Merchant Company with their *many* ears inherited this wondrous gift of transforming £26,265 in the year 1867 into £45,000 in the year 1868?"

LARBERT.

The Scottish National Institution for the Education of Imbecile Children has at present within its walls fifty-eight children of various ages. Dr. Addison is the Medical Superintendent. It is said that he has a gentle touch and a pleasant word for all, and they brighten up with evident pleasure when he approaches. With increased funds greater good could be done.

DUNDEE.

The spinning and weaving trade is in a depressed state in this town. It was agreed to adopt short time by way of reviving it; and as there was a large amount of distress, it was resolved to establish a soup kitchen for the partial relief of those who required aid.

ST. ANDREW'S.

By the munificent bequest of the late Colonel and Miss Wilson, about ninety tons of coal have been distributed amongst the deserving poor of the parish last week.

SELKIRK.

At the usual monthly meeting of the Town Council, Provost Anderson reported that the committee appointed at last meeting of Council to watch over the St. Mary's Loch Water Scheme had met with the manufacturers and others interested in the matter, and that the feeling of the meeting was decidedly in favour of opposing the measure. To carry the water from St. Mary's Loch to Edinburgh would, he said, be to take away the natural supply of Selkirk, and he recommended that the Council should petition against the bill promoted by the corporations of Edinburgh.

Mr. Bathgate said he disclaimed anything like hostility to the people of Edinburgh, but it seemed to him as if they entirely ignored the wants of this district.

THE WEATHER.

An M.D. in Ross-shire, writing on this subject, says:—

"If the Gulf Stream—a current of the ocean—brings with it not only a warmer water to our shores, but occasionally the products of a tropical climate, why may not a current of the atmosphere do the same? Whence the occasional tropical birds, perhaps also the mosquitoes? And was the bad form of typhus fever, so fatal in some localities, but a modification of *yellow fever?* Who yet knows what fever poisons really are—whence the actual sources of fever—and how to class and even name them?—a question decided only by the Registrar-General for the sake of classification in his returns."

EXPENSE OF THE NEW WATER SCHEME.

This subject was discussed at the last meeting of the Edinburgh Town Council. Several motions were made, but at length the Council was counted out before a division was taken.

It was debated again at the quarterly meeting of the Edinburgh Chamber of Commerce and Manufactures. Plainly it is a subject on which much difference of opinion exists.

The Royal Scottish Society of Arts held its usual meeting on the 11th instant, in the Hall in St. George street, when, at the request of the Council, Professor Fleming Jackson delivered an Address on "Technical Education."

A **banquet** was given on Thursday night by a large and influential company, in the Douglas Hotel, to the Right Hon. the Lord Justice-General, in honour of his election to the Chancellorship of the University of Edinburgh.

◆

GERMANY.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, DECEMBER 31.

There are in Austria a good many physicians who seek their specifics after the Hahnemannian dogma, *Similia similibus curantur.* And the following is the latest application of their practice and teaching:—

1st.—Each new remedy must be examined by many persons, who take it internally.

2nd.—The symptoms which are observed in the majority of the examinations are called *pathogenetical symptoms*, and when they are found in invalids with the same temperament or age, resulting from the same reason, aggravated or ameliorated by the same conditions, then they are also the characteristic symptoms for the remedy, and will cure the patient.

3rd.—The *dose* for the invalid should be always much smaller than the least which produced a pathognomonical symptom. It can vary from the original substance (mother tincture) to the thirtieth dilution or trituration of Hahnemann. Ozanam asserts that spectral analysis can detect the substances in the tenth dilution (!)

4th.—It is not allowed to mingle two remedies in the same prescription.

5th.—When a remedy had produced an effect of the same kind (a violent one is a very good sign of crisis) it must be stopped immediately, and should not be continued until the effect is passed.

6th.—When amelioration takes place the remedy must be administered less frequently.

But the homœopaths of Austria are not yet united. They have, like Protestants, different sects. One follows implicitly the dogmas of Hahnemann, others desire to combine them with the principles of modern science. The homœopaths have a society of which each member is obliged to prove a remedy on his own body. The little societies in the single towns or provinces have their centralisation in a central union, which has its residence at Leipzig.

The homœopaths have three hospitals at Vienna and two clinics; but they have lost in late years their leading men, also in the different provinces of Austria they have hospitals and societies for proving remedies. The president of each society gives to each member a phial full of a substance which is known but by himself. Members do not learn the name before they have all tried the remedy on their own bodies, after having described beforehand the state of their health, temper, occupation, manner of life, and having analysed their urine, which they continue once a week.

At Ling, the capital of Upper Austria, happened the following interesting incident. It must be *unicum in historiâ.* Two of the first physicians called into consultation one of the homœopaths, requested him to continue the treatment of a case of scirrhus of the stomach in a countess, and begged him to allow them to meet him at his visits and to see prescriptions.

The hospitals at Vienna are seldom visited by students of medicine, only by the doctors who have already finished their studies. The Austrian homœopaths have their own journal, as the central union at Leipzig its own. In Austria it is allowed to the homœopathic physicians to *dispense* their remedies themselves; in Bavaria and Saxonia not. At the great congress of German naturalists and physicians held at Carlsbad, Dr. Hoppe (not homœopath) proposed that every physician—to whatever school he may belong—should have the right to dispense himself, if he desire, the remedies he prescribes. In former times that right was possessed by all physicians. The traditional school of medicine at Vienna and in Austria continues in the old paths. Its disciples are very numerous. They mingle the principal remedies—the *adjuvans*, the *excipiens*, the *corrigens*—and sometimes two or three of them (any of which could do good in a doubtful case)—all these in one mixture, or ointment, or plaster, and the higher the dose the greater they think will be the good effect. They bleed by phlebotomy and by natural and artificial leeches; they put on sinapisms and blisters; they use dry and bloody cupping. These and other means they prescribe at the same time, not wasting time by waiting for each of the various remedies to show or develope its own effect, as they do not believe it is destroyed by the dose being repeated too often, nor by remedies given at the same time, as chemical agents, antidotes, &c. For whatever disease, when there is constipation, a purgative is given at the beginning, and this is repeated when needed during the treatment. When there is much pain, opium, or morphine, or cherry laurel is given. Sometimes these palliatives are abused, and this has been the case more since the introduction of the plan of subcutaneous injection. Morphia is constantly used by this method by the first operator and professor of surgical clinic at Pesth, Professor Balassa.

The new physiological school of Vienna, called sceptic, nihilist, or expectant, has separated itself entirely from the good old traditional or palliative school, and is said to sympathise to some extent with the homœopaths. The physiological school condemns (in principle at least) the mingling of many remedies together, and prefers simple prescriptions, many of them being convinced that the "do nothing" is safer than the "do anything" plan. They say globules contain nothing more than sugar, therefore are equal to zero. The expectants avoid pretence, and conscientiously give nothing; but the homœopaths give nothing, and say, notwithstanding, that they have given something. They respect diet and regimen as much as homœopaths, and attribute all the good results of the last to careful regulation of them. Therefore the physiological school says the homœopaths are not stupid, but they are cunning charlatans, whilst the old traditional school says the homœopaths are both imbeciles and charlatans.

In conclusion, the Vienna modern school resembles the state of Spain after the banishment of Isabella. They have pushed down many of the old columns of the temple of Hippocrates; they still try every column which is not thrown over to see whether it is firm or upright. Even one of the greatest friends of the modern school, the poet Frankl (himself a physician) has described the state of anarchy in the medical kingdom. In "The Modern Hippocrates" he castigates with caustic satire the errors of all the different schools, and principally those of the physiological, of which the aim is to verify correct diagnosis by *post-mortem* exploration: treatment is their last care.

They have pushed down the old gods, but do not know what new god they should put on the throne in place of the old. The revolution is not complete.

Now, not to dwell too long on these hostile schools, let me introduce a trifle of a practical kind in regard to diphtheria. This is desirable, because in my next letter I wish to describe another school, and then in another the many specialties that exist in Vienna.

The egg of Columbus in treating diphtheria.—The observations of Hallier, at Jena, teach us that the chief cause of diphtheria and other diseases is attached to a volatile contagium—that is to say, the seeds of a fungus; and Dr. Grauvogel, chief physician of the military hospital at Nuremberg, discovered that they are to be found principally at the union of the posterior part of the nose with the posterior part of the mouth—both passages for the air. He found that touching them with alcohol (spiritus vini rectificatus) is the best remedy; that whenever spirit of camphor did good to anybody, it was not the camphor but the spirit of wine, because every good housekeeper knows that the fungus on the surface of her preserves is destroyed by brandy or any spirit. In order that the alcohol could reach each part of the mouth, and the posterior parts of the nose and pharynx, Dr. Grauvogel advises us to employ the vapour of alcohol by means of atomisers (*pulverisateurs*). Dr. Zwingenberg, in Brandenburg, saw in the epidemic of 1867 that that species of diphtheria which is to be found in low regions, in damp houses, damp seasons of the year, or during heavy rains, was absolutely cured by this plan. He says—"As soon as I remarked diphtheria I gave the advice to touch most of the spots with alcohol by means of a camel-hair brush. This is to be repeated every hour. In individuals who are old enough to be reasonable I order to rinse the mouth with a liquor composed of one spoonful of tepid water and five drops of alcohol. In the very young or the very sick this may not be practicable. Interiorly I give mercury. Subsequently I order for each poor patient a small portion of brandy to take in the mouth after dinner; for the rich I order red wine. Children must rinse the mouth every day several times with tepid water containing some drops of alcohol; or when they are rich, instead of alcohol good *claret* may be used." Under this plan no relapse ever took place.

There are specialists for the diseases of almost every organ at Vienna. First, for the diseases of the skin there is the greatest authority, not only in Vienna, but in the whole of Europe—except England, France, and Italy—Professor Hebra, a fat, short man, with a remarkable boldness and sincerity in speaking. His lectures are visited and diligently followed by all nations, except those of the Latin race; principally by Swedes and Norwegians. He has a great hospital at his disposition for demonstrations, and each man is presented undressed, but the women only expose the affected parts. His work on the diseases of the skin is accompanied by plates most skilfully painted after nature by a physician who was at the same time a great artist. The work was printed at the expense of the Academy of Sciences. I heard him (who does not believe at all in homœopathy, but hates it less than the orthodox school) apostrophise his audience, when speaking of acute exanthems, thus:—"Gentlemen,—I beg you particularly not to treat these diseases by another method than by homœopathy; that is to say, *do nothing!*" And on speaking of chronic skin diseases, especially eczema, he quoted a case which could not be cured by him. The patient did not return for a long time. Finally he met him in the street and found him quite cured, and asked how he was cured. He answered, "*By homœopathy.*" The professor remarked on this—"But do not believe that it was the remedies; not at all—but the regimen, the abstinence from all external treatment, particularly from water and ointments."

Notes on Current Topics.

The Poor-law Board and the New Ministry.

There are few departments of State in which our profession has a livelier interest than in that of the Poor-law Board, and a change of Ministry is to hundreds of hard-toiling medical men a source of hope that their cries for justice may be heard. We have certainly been surprised at the tone adopted by some of our contemporaries respecting the accession of Mr. Goschen to the office of President of the Poor-law Board. The right hon. gentleman is not one who is likely to consent to be a mere puppet in the hands of a permanent secretary. He has proved his capacity to understand and manage a great commercial undertaking, or an important State department, and he certainly contributes to the Cabinet his full share of influence, knowledge, and honesty. Those, then, who were crying out that nothing could be worse than the last President, might well welcome Mr. Goschen, and we are confident he will be found superior to all those who have been tried and found wanting in office, though ready to give promises in opposition. The right hon. member for London will not tolerate such jobbing as disgraced the dying days of the Tories' official career. He is fully sensible of the want of a strong head of this department. He can grasp the figures and the facts with which he will have to deal. This is clearly shown by his sensible speech on his re-election. There he recognised his responsibility in a manner his constituents will appreciate; and we hope the medical profession will find that a Liberal statesman at the head of the Poor-law will lead to some of the results for which we have so long struggled. That he knows what is expected of him, and is not likely to shirk his task, is clearly evinced in the following extract from his speech on returning thanks for re-election :—

> "I have been called to fill an arduous and responsible office. I do not disguise from myself the full weight of that responsibility. Constantly increasing rates, constantly increasing pauperism, millions of money spent, yet without satisfaction, and, infinitely worse, millions of human beings whose very name implies a degradation even in their own eyes, as recipients of parochial relief—such is the subject-matter with which a President of the Poor-law Board is called upon to deal. His sphere is on the dark side of our social system. His province is what I may call the bankruptcy of the million, and it appears to me that the Poor Law, like the Bankruptcy Law, can never give complete satisfaction, because both deal with something deplorable in itself. The utmost we can expect to obtain is to make the best of a bad job. I hope and believe that much may be done to grapple more effectually with that which is a growing evil, for I must speak of a growing evil when we have to face the terrible fact that, in the short space of two years the pauperism of the metropolis has increased twenty per cent., and that not less than 30,000 paupers—a number equal to the population of a good-sized town—have been added to the numbers of those who, I might almost say, are closing in upon the industrious portions of certain districts of London, till the ratepayer of to-day himself becomes the pauper to-morrow. I hope and believe that great improvements, both legislative and administrative, are possible, for public attention has been awakened to these facts, the action of Parliament has been more decided, and the labours of my predecessors have done much to loosen the ground; but those who ask for impossibilities do much to make impossible that which might otherwise be possible. The Poor-law Board always stands between two fires—between the honourable zeal of the philanthropist, on the one hand, and the prudent warnings of the political economist on the other. It was stated, I observe, at a meeting the other day, that we might dispense with the Poor Laws altogether if the Government would but employ all those who wanted employment—if it would take charge of the young, the old, and the infirm. Now, that is what I call asking for impossibilities. (Hear.) Government action can never be substituted for the 'whole duty of man.' You cannot expect Government to take the place of thrift and self-reliance, of family ties and parental care, and doctrines that encourage such views do not point to the cure of pauperism, but pauperize the mind as well as the body; and benevolence may wake up one day to find itself denounced as socialism in disguise by its warmest advocates. The duties of the Poor-law Board are serious enough without this imposition of impossible functions The one practical difficulty with which it has had to contend from the first is not the degree of expenditure, not the degree of sternness, but how to discriminate and classify the classes with which it has to deal,—to discriminate between the innocent, the helpless, and the temporary pauper, and the confirmed vagrant, and the hopeless idler. (Hear, hear.) Directing itself chiefly to this, I believe much may be done to discriminate between the class to whom charity is a blessing, and the class to whom charity is a curse. (Cheers). Till that is accomplished we shall pass through a cycle of reactions—cries for more humanity and more expenditure at one time, and cries for a more stringent and deterrent system at another. As long as the gigantic machinery which is employed is so coarse that it cannot discriminate, so long will this state of things last; but it takes time to adapt such machinery and make it sufficiently delicate to sift the materials with which it has to deal. Other difficulties ought not to be so serious. The ratepayers from whom so many millions are exacted, have a right to demand that the mode in which those millions are raised and distributed should secure as great attention and care as a system of imperial finance. I have on several occasions spoken on this subject of local taxation, and I do not wish to rebut a single word. I know that impediments are in the road at every turn, and that we have much uphill work before us. It sometimes happens, however, that the traveller who looks along a straight road sees so steep an incline at the end that he thinks the coach will never be pulled up, but when he comes to the foot he finds it a gradual ascent which a strong pull can conquer. What may be my fate in this respect I do not know, but one thing I can promise you while thanking you for my re-election—it is that I will not shrink from the collar."

Hair Dyes and Cosmetics.

Some hair dyes are innocent enough, and do not require any warning on the part of the medical man; others are dangerous, and the use of both kinds requires tiresome manipulations. Among the innocent kinds we may mention infusion of beans, and cypress cones, of willow bark, and ivory black. Among the second kind may be enumerated sulphate of lead, mingled with hydrate of lime and water; carbonate, acetate, and sub-acetate of lead in solution, to which dilute sulphuric acid is added, and which dyes the hair a dark brown. The salts of silver, too, are much used to blacken the hair, but they make the scalp irritable, and burn the skin and the hair follicles, and tend to produce baldness. Among the formulas mentioned are (1) acetate of lead, gr. xxx.; carbonate of lime, gr. xlv.; quick-lime slaked, gr. xl.; or (2) oxide of lead, two drs.; slaked lime, one ounce; starch, one ounce; and solution of potash, two drs.; (3) nitrate of silver, two drs.; bitartrate of potash, two drs.; feeble ammonia, four drs.; and lead four drs.; (4) nitrate of silver and photo-nitrate of mercury, of each four drs., to four ounces of distilled water.

Such are the recipes most used by the hair-dyers of Paris and elsewhere; and it is evident that lead poisoning might easily be contracted by the use of those which contain the oxide of lead, and, as before remarked, that baldness would be likely to be favoured by the use of those containing nitrate of silver. Certain substances are used for changing the colour of the skin; for example, the white cosmetics, bismuth, or pearl white, is sometimes mixed with a notable quantity of arsenious acid, when it is dangerous; but when this substance is purified, it is innocent. A cosmetic, named Thénard's "fard," is composed of zinc flowers and talc in equal proportions, and is the best and most innocent cosmetic. The common white "fard" of the theatres is dangerous, containing as it does carbonate of lead. With regard to red colours or cosmetics, Brazil wood and cochineal may both be employed without danger. The carmine of Germany or China, too, is innocent, whilst rouge containing mercury is much to be avoided.

A great deal of interest has of late been attached to the subject of cosmetics, probably through the trial of a well-known "artiste" in this department. A correspondent of the *Times*, for instance, had one of the hair dyes analysed, and found it to be composed of rose-water, sulphur, and acetate of lead; the latter in sufficient quantities to cause painter's colic or paralysis. The subject requires investigation, and if possible a harmless hair dye should be constructed to satisfy the demands of the fair sex, to whom, in the present state of human progress, the possession of grey hair is often a great misery.

Stimulant Extras in English Workhouses.

It would appear that the English Poor-law Board recognise in the relieving officer the capability to decide on the propriety of granting extras for patients who are in want of stimulation or support, for they have decided that he is empowered to refuse the "extras" ordered by the medical officer on his own judgment. Dr. Fitzpatrick, of the West Derby Union, it appears, recommended additional nourishment to patients whom he considered in want of them, and the relieving officer refused to carry out the order. The Poor-law Board have decided that the relieving officer may so refuse, but that "the recommendation of a medical officer as regards the supply of 'extras' is entitled to great weight, and it is not expedient it should be disregarded by the guardians, unless it appear that what is ordered is improper in its nature or excessive in quantity, or that the person on whose account it is ordered is in a position to provide it at his own cost."

It is difficult to suppose that any non-professional person can be competent to say when the time for stimulation in disease has been reached; and as long as it depends on a harmony of opinion between the medical officer and the relieving officer, without doubt cases must arise when the patient will be the sufferer from a disagreement.

The Value of a Parish Doctor.

A DECISION, which savours very strongly of Irish Poor-law generosity, has been arrived at in the case of Kennedy v. Ness, lately heard, on appeal, before the Lord President. Dr. Kennedy had been engaged by the guardians of the East Wemyss Union to discharge extra services during the cholera epidemic. To the death he kept to his bargain, for he took cholera in the discharge of his duties and died. His executors furnished thereupon an account to the guardians for £130, being at the rate of £3 per day, which demand the guardians of course disputed. Last year the case was tried by the Lord Ordinary, Lord Jerviswoode, who thought the demand was not excessive, and scouted the suggestion that the inability of the poor to pay, or the number of the patients visited were relevant to the matter. We observe with great regret that this decision has been reversed.

The Lord President has awarded £65 as payment in full for labour, hardship, disease and death! If so, what should be paid for the reading a brief in a comfortable easy chair? About threepence. And yet Lord Jerviswoode has often got a hundred guineas and indefinite "refreshers" for the work—just the value of two parish doctors.

The Prevention of Syphilis.

THE report of Dr. Barr, the Medical Officer for Aldershot, to the War Office on this subject has lately appeared, and it informs us that the working of the act at the camp continues to prove most satisfactory. Out of 1,147 periodical examinations of women, a larger number than that of the previous quarter, 209, or about one in every five, were found to be diseased and sent to hospital. The propriety of intercepting so large a proportion of disease as that which exists in one-fifth of the entire number of women needs no argument or proof. These 209 *foci* of disease would, in every probability, have extended the contamination to 2,000 before many days were over, and in process of time the appalling proportion would be reached which has at length compelled action in the matter.

Medical Brummagem.

WITH the trifling exception that the medical profession on the other side of the Atlantic does not pay for the perpetuation of abuses by a do-nothing Council, they appear to differ little from ourselves in the diploma traffic. To found a University and confer licenses to practise seems with Brother Jonathan to be as easy as the opening of a goods store, and the wares which mock Licensing Corporations are as ready to a purchaser as a dollars worth of any article of trade. Mr. Henry Ward Beecher, in a recent address, brought these facts into a most desirable condition of notoriety by reading the following letter addressed to him by one of his flock :—

> "DEAR SIR,—I take the liberty of writing to you to inquire if you know anything of Professor ——, and of the —— Medical University. I wrote to Professor —— asking him his terms, and he has replied, telling me that he can fit me for the practice of medicine in three months, charge $200. I desire to study medicine that I may be enabled to lessen some of the sufferings that I see about me, and as there is no one in New York whom I know personally, I thought I would write and ask you whether I can depend upon what Mr. —— has written me, and if the graduates of the —— Medical University are able successfully to practice the profession of medicine. I will feel deeply indebted to you for any information relative to the above."

Our virtuous indignation at the existence of this abuse is by no means untempered with a feeling that we are not separated by 15,000 miles of sea from such practices. We are not so far away as we imagine from licensing bodies whose diplomas can be earned by three months "grinding" on the part of any person of reasonable smartness, nor from enterprising crammers who will undertake to squeeze a student through the pseudo examination for even less money than the 200 dollars, or in even less time than the three months. Let us not satisfy ourselves with the consideration that the "vile bodies" on which persons thus washed in the medical gilding bath are to work out their subsequent education are far away from ourselves. They are not so, for we have in Great Britain the brazen alloy of which such practitioners are made—gilders who can give the gloss without wasting the millioneth of a grain of real metal, and the corporate assayers who are ready to give the hall mark without too rigid a test.

English Medical Assistants.

MR. BAXTER LANGLEY, in a communication to a contemporary, furnishes us with some figures which are very instructive as evidencing the attitude of the profession on matters of qualification. During the year 1868 Mr. Langley had 956 applications from medical practitioners for assistants, of whom 516 wished for qualified, and 440 for unqualified pupils.

Mr. Langley says :—

> By comparison with three previous years, it would appear that the demand for qualified assistants had increased, and that for unqualified ones had decreased. In the meantime, salaries have greatly advanced, the position of the medical assistant has been improved, and the demand for English qualified in-door assistants now largely exceeds the supply. To illustrate this fact, I may state that I have on my books 42 vacancies for qualified assistants, and 32 for unqualified. In general terms, the demand for unqualified assistants (except in large towns) is dying out.
>
> The state of affairs in some colliery and mining districts is quite exceptional, and I could produce overwhelming evidence to show that the tendency is general to employ qualified men only. But then arises the question. Where are they to be got? As a rule, the Englishmen now entering the profession have either money or prospects, and do not enter upon the duties of assistantship, and the chief supply is from Ireland and Scotland. The former constitute by far the larger number, and are found to make good assistants when they have mastered the details of that apothecary's work which is performed by the majority of English practitioners.

The London Hospital.

The total number of in and out-door patients treated at this hospital during the past year was 45,636, of which 4,932 were in-patients. The free out-patients who required continuous treatment amounted to 18,491; these included accidents, renewals, and maternity cases. There were 3,831 not generally requiring continuous treatment, besides numbers in the "special department," comprising skin diseases, and dental and ophthalmic cases. During the prevalence of diarrhœa, the number of applicants for medicine—not included in the above return—amounted to 15,682. From these figures it will be seen what an amount of unpaid work is done by the principal medical staff in only one of these valuable and benevolent institutions. If, however, we glance over the area of the metropolis, and think of the various hospitals and dispensaries--in some of which quite as large an amount of assistance is rendered as in the one to which we have referred—it will be seen that, as a class, the medical profession is far in advance of all others in the gratuitous disposal of its efforts for the benefit of the sick poor. Others give the money for the support of these institutions; but it is their skill, their time, their energy—without which the money would be valueless—which these men devote to the relief of the needy and otherwise helpless members of the community. It is easy for those who have plenty to put their hand into their pocket and present the guinea, or even the five guineas, to the collector when he calls; but it involves a large sacrifice of time and self-interest to attend the hospital day after day, to watch through the wards and prescribe for the patients who lie suffering there, or attend them at their own miserable abodes.

The Vaccination Act.

The difficulties that attend public vaccination have given rise to many proposals for legislative action. Amongst these should be noticed a plan recently put forth of confiding this operation entirely to public officials. This would take the operation out of the hands of the professional men of the kingdom. As the public vaccinator would be prohibited from private practice, many disagreeable circumstances would thus be got rid of. There are, however, a good many general practitioners who derive a considerable proportion of their income from vaccination, and who would not like to be called upon to relinquish either that or their private practice. They would, therefore, as a matter of justice, have to be compensated. Many of them would, we have no doubt, accept the new appointments were the salary made such as a medical man has a right to expect. There is still another question. Amongst the many, especially physicians and accoucheurs, who would gladly be relieved from the duty of occasionally vaccinating the child of an intimate friend or particular patient, there are some who feel the necessity of doing so. Certain people would strongly object to any but their own attendant performing this slight operation, and they have a right thus to object. So long as the operation is properly performed the State has no right to dictate further. At this moment every qualified practitioner is entitled to vaccinate as a professional act, and we cannot think Parliament will abridge his rights. The certificate of any registered practitioner ought to be conclusive evidence that a child has been properly vaccinated. The public vaccinator might have this sent to him in such cases, and from it he could fill up the other required forms as if he had himself performed the operation. We doubt, however, whether either the public or the profession would like to see the scheme tried at all.

The Repetition of Prescriptions.

The following resolutions from the American Pharmaceutical Association relative to this question were presented and read before the East River Medical Association of New York:—

"Resolved—That this Association regards the pharmacist as the proper custodian and owner of the physician's prescription once dispensed.

"Resolved—That however desirous we may be to accede to the request of the East River Medical Association, the restriction of the pharmacist to a single dispensing of the prescription, without the written authority of the prescribing physician for its renewal, is neither practicable, nor within the province of this Association. Nevertheless, we regard the *indiscriminate* renewal of prescriptions, especially when intended for the use of others than those for whom they were prescribed, as neither just to the physician nor to the patient, between whom we stand as conservators of the interests of both, and that such abuses should be discouraged by all proper means."

In response to which the following resolutions were unanimously adopted:—

"Whereas—The Pharmaceutical Association, after acknowledging that the renewal of prescriptions is unjust both to the physician and the patient, declares that it is not within its province to prevent such renewal; therefore

"Resolved—That the State Medical Society be requested to ask the next Legislature to pass an Act making it a misdemeanour to renew or use a prescription without the authority of the prescribing physician."

A contest between the physician and the apothecary as to the possession of a prescription to which neither of them have the remotest title, will, no doubt, be amusing to our readers. That the physician should invoke legislative aid to prevent his customer from using that which he has sold to him, is almost as ridiculous as the pretension of the apothecary to make a general use of the recipe which is the purchased property of his customer. Such disputes are unseemly, and suggestive of a voracious appetite on both sides for money value of a prescription.

It is apparent that the medical adviser, having received his fee, has no right whatever to dictate to his patient how often he shall avail himself of the advice he has purchased; and it is equally patent that for the apothecary to use a customer's recipe for any other purpose than the dispensing of it in that individual case is a deliberate fraud. The patient alone has any title in the prescription.

Pauperism and its Causes.

We have been informed that, at a late meeting of the Dialectical Society of London, a Committee has been formed, consisting of several well-known names, among whom are several gentlemen of the medical profession, for the purpose of discussing the causes of the distressing pauperism so common at this juncture, and endeavouring to suggest remedies both for alleviating the present misery, and for preventing the chronic distress and degradation from being of such constant recurrence. We have no doubt that this Society will attack the subject fearlessly, and that all sides of this important, nay, vital question, will be heard by this Committee before coming to a conclusion.

Royal South Hants Infirmary.

LADY PALMERSTON, accompanied by the Viscountess Jocelyn and the Viscountess Sudley, visited the Royal South Hants Infirmary last week, and expressed themselves highly pleased with the great neatness and order which prevailed throughout the Institution.

ON Wednesday last a General Court of the Royal Humane Society was held at the offices, Trafalgar square. It was stated that sixty-five persons were taken from the water in Hyde Park during the year, forty-nine of whom were successfully treated. In general cases, out of 363 persons taken from the waters, 337 had been restored to life.

DR. WINTERBOTTOM, a venerable medical man belonging to the seaport of South Shields, left a sum of £27,000 for the purpose of erecting a College for Seamen. The building, which is a very noble one, was opened on the 12th inst., and dedicated as a free college for the education of seamen in navigation, and all the branches of scientific knowledge useful in their calling.

IN London alone scarlet fever has destroyed fifteen lives, of children chiefly, every day for the last thirteen weeks, or 1,324 lives in the aggregate.

MEDICAL inspection of artisans' dwellings in various parts of London shows that they are dangerous to health and unfit for human habitation.

THE estates belonging to Browne's Hospital, Stamford, have increased from £800 to £1,700 a year, besides 850 acres of land and twenty-five or thirty houses, of which the leases have not expired. It is thought the trust will shortly be worth £4,000 a year.

IT is a somewhat singular fact which appears from a Parliamentary return just issued, that the consumption of spirits per head in the United Kingdom is the same now as at the commencement of the century. We are not, therefore, as a nation more intemperate now than then.

LUNACY appears to be slowly increasing in Essex. The number of inmates in the County Asylum at Christmas, 1862, was 498, while at the same period in 1868 it had reached 599, by regular gradation through the intervening years.

A MEDICAL friend informs us that variola is very prevalent in Manchester at the present time in the Bacup district, and that it is of a very severe type.

Le Figaro says that Prince Napoleon's condition is becoming more serious. He has had a return of the fever. For forty-eight hours the Prince was delirious.

SEVERAL legacies have been received during the past year by the Committee of the Devonshire Hospital:—£261 5s. 10d. from the late Mr. Sharman; £45 from Mr. A. Greenwood; and £250 from W. Gibson, Esq.

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. VIII.

I WAS "at home" at last—from nine to eleven a.m., and from seven to ten p.m., daily; unfortunately, too, I was "at home," as a rule, from eleven a.m. to seven p.m., for, alas! I had no out-door patients to visit.

Sanguine as my expectations were, and brilliant as my prospects appeared, still I possessed sufficient *mens sana in corpore sano*, to enable me to deduce, from a limited experience of the "world" and of its ways, that a very large share of the section of it, the district wherein I "settled down," formed, had to discover, if not my very existence, the meteoric properties I possessed; and, until the time of such discovery, professional visits to or by me perhaps would be limited in number—a circumstance that I considered more advantageous than otherwise, as it would afford me some time from professional pursuits, in order to trim and to decorate, in first-class clipper fashion, my establishment.

'Tis true, however, that I was prepared to receive and to be satisfied with limited patronage, so as to "open the ball," allegorically speaking; but I was not prepared to experience the disheartening, if not the disastrously disappointing, feature my affairs put on, just at the time I presumed that I was about to mount the glittering chariot of fame, and to whirl along in spanker fashion (destination not known) over the magnetic road of fortune, regardless, 'tis true, of beacons, lights, and signals—regardless, too, of the machines my impetuosity might tilt or turn over. Alas! many weeks elapsed from the commencement of my occupancy, and of the issue of my professional programme, and I neither received nor was I solicited to pay a solitary professional visit.

To what stage of hopeless despondency and physical desperation I should have ultimately drifted, only the gods know, but for the timely arrival of Mrs. McPherson. Mrs McPherson was my first patient. She suffered from cough, night sweats, thoracic pains, loss of appetite, loss of flesh and considerable amount of prostration. Mrs. McP. on several occasions coughed up blood. Poor lady! her husband, after an illness of many months, died of phthisis, and left her without means, but with four children. I prescribed for, and impressed on her the necessity of at once recrossing the Tweed, if she had any relatives beyond it, gave her a note which she desired, in order to present it with others to that society of benevolent and humane Scotsmen which (I *now* know) meet occasionally in one of the wonderful sinuses that anastomose with Fleet street,—namely, Crane court. Mrs. McP. was assisted by the society of benevolent and humane Scotsmen, and by others too, and recrossed the Tweed, accompanied by her children, in order to complete preparations for a prosperous and, let us hope, a happy journey.

Mrs. McP. lingered for a long time, and, notwithstanding great sufferings, availed herself of many opportunities to write and to express her gratitude for the interest I took in her case—an example worthy of imitation this side the border.

The second visit paid to me was by a police constable. He complained of headache, pains in back, vomiting, quick pulse, and foul tongue, and questioned the opinion of the Divisional Surgeon, who declined to certify that the constable was unfit for duty. Need I state that he was in the incipient stage of variola, from which dire and treacherous disease he only scrambled through, but not with a *whole* skin ?

It is necessary to note that the Divisional Surgeon did not examine this constable, he merely looked at him ; and as malingring was at that time a prevalent complaint in the force, the surgeon, let us say, thoughtlessly, assumed the constable's illness to be of that type.

The third visit paid to me was by the pot-boy from a neighbouring public house. He submitted a "bad" finger for my opinion from himself, and a list of empty pots, with an account current for sundry full ones sent to *the* premises since I became "man in possession." Being strictly temperate myself, the very sight of this account caused me to become highly indignant. I repaired his finger, however, and referred him to "one storey up" for pots and for payment ; the former he received, the latter he did not, then, nor since.

The first visit I paid was to a "wise woman," of the type "fortune teller." "She were took in a fit frightful, and we sent for you leastways she might go off in it, Sir, being neighbours like," as a rotundo-shaped woman, garbed in a rusty-coloured material, and emitting the odour alcoholic as she spoke, informed me. I found the "wise woman" doubled up on her parlour hearthrug, drunk as Chloe ; even in liquor she displayed wisdom, for she was silent, or nearly so. Some playing cards, a writing slate, a pencil, a brandy bottle, and two seriously damaged tea-cups were in a cluster on the small deal-topped table that stood in the centre of the apartment ; this table, together with three or four very dilapidated cane-bottomed chairs, and a couch down at two legs, and with the "alva" protruding through many portions of it, not unlike so many "frizzettes," now so numerously displayed in the windows of our fashionable coiffeurs, and which the ladies of our period avail themselves—constituted the room's furniture and her stock in hand of "household gods." It was highly essential that I should pay some visits to this wise woman, and by proper treatment improve her bodily condition, for it was poor, indeed.

Stretched along the hall passage of the house whereat the "wise woman" resided was a seat of many feet in length, and I never beheld that seat unoccupied. I had no idea *then* of the vile traffic in which my patient engaged. Subsequently I learned that her daily receipts, principally in small sums, varied from five to *twenty* shillings, and her daily expenditure for drink and "living" fully equalled it, so that she was always in debt. I sent my bill in due time ; the wise woman denied her responsibility for the debt, as *she* did not send for me, nor "did she think it would be near so much." My boy, Limbo Pod, or Boey, pertly replied that if she "wor a complete fortune-teller" she should have known beforehand what sum the doctor would charge, on hearing which decidedly bold expressions to her professional disparagement, the wise woman seized Boey by the collar and by the breech, and, having "show'd him London," shook him up like a bag of bones as he was, led him by the ears to the entrance door and propelled him down its steps (to sprawl on the foot-path), by means of an elevated foot and slipper. That "wise woman" is dead. There is *now* another "wise woman" in the same neighbourhood, professionally fearless of police and the penalty consequent on detection. She reads, by means of knaves, fives, kings, queens, and aces, the human destiny. She is little over forty years of age, good-looking, inclined to be *embonpoint*, temperate, and frugal. She is paid by her clients on the voluntary principle.

Quid Nunc.

Summary of Science.

PHARMACY.

CARBOLATE OF QUINIA.

Professor Wenzel proposed to use a mixture of carbolic acid and quinia. However useful this may be from a therapeutical point of view, there can be no doubt that it is an unchemical mixture. He says that with bases, even weak ones, such as quinia, carbolic acid loses its irritating properties. This compound is prepared by dissolving 60 parts of carbolic acid with 100 quinia, in 300 of rectified spirit, filter the solution, distil, and evaporate to the consistency of turpentine. Make into pills with cassia.

ADULTERATION OF MEDICINES IN AMERICA.

The *Pharmaceutist*, an excellent paper, and the organ of the Chicago College of Pharmacy, contains the first of a series of articles upon the above subject, by which it is evident that they are even worse off in America in respect of this crying abuse than we are. The following are the articles examined :

Epsom Salts.—Spurious article, consisting of finely crystallized Glauber's salt.

Sal Rochelle.—Specimens contained 25 per cent. of sulphate of soda.

Glycerine.—Impure, and adulterated with sugar.

Black Sulphuret of Antimony consisted mainly of galena (sulphuret of lead). These are now old-fashioned adulterations, which would not pass muster in this country now. There is even a refinement in roguery.

Lemon Juice.—This substance, which has been especially brought before the public by the regulations of the Board of Trade, has been carefully examined by Mr. W. Stoddart. His paper is certainly the best that has appeared upon this subject.

The specific gravity and percentage of citric acid differs according to different authorities :—

	Specific gravity.	Grs. per oz. of citric acid.	
Pereira	1·77	 10	
British Pharmacopœia	1·039	.... 32·5	
Muspratt's Dict.. ...		.... 31·	(very superior)
Watts' Dictionary...		.... 20½	
Board of Trade, not less than	1·030	 30	(not less than)
Lemon-juice, fresh, Feb. 26, Stoddart	1·040	.... 40 to 46	
Same fruit, after six months	1·027	.... none	

Analysis showed that the citric acid had all split up into glucose and carbonic acid. Afterwards, the nitrogenous matter in the juice having set the whole into fermentation, the glucose produced alcohol and acetic acid. Freshly prepared lemon-juice is an aromatic, thin, milky, slightly yellowish liquid. When it is kept for a few days, it acquires the mouldy flavour, which the commercial juice usually possesses. Trummer's test gives a decided indication of glucose. With polarised light, the ray is turned to the right. Acetate of lead gives a muddy precipitate (gummate of lead). Chloride of barium, acetate of potassium, or chloride of calcium, should give no precipitates indicating the absence of sulphuric, tartaric, or oxalic acids. The aroma from the pure juice is very peculiar, and differs as much from any artificial compound as rose-water distilled from the petals does from otto.

"All chemists are aware," says Mr. Stoddart, "that when citric acid is fused with potassa, it is decomposed in oxalic and acetic acids :—

$$\underset{\text{Citric acid.}}{C^6 H^8 O^7} + H^2 O = \underset{\text{Oxalic acid.}}{Ca^2 H^2 O^4} + \underset{\text{Acetic acid.}}{C^2 H^4 O^2}$$

But when liquor potassæ is mixed with common lemon-juice, in the cold, oxalic acid may be detected in a few days."

The analysis of many specimens of ash shows only 3-10th grain of potash per ounce. Those who advocate Dr. Garrod's view, that it resides in the potash, must have a homœopathic idea of value, and plenty of faith.

THE FIELD WORK OF WOMEN AND CHILDREN.

We have before us the "First Report of the Commissioners on the Employment of Children, Young Persons, and Women in Agriculture, presented to Parliament by command of Her Majesty." We venture to predict that the labours of this Commission will falsify many of the anticipations of those who have thought upon the subject, but have not a practical experience of it. Even this first instalment contains passages which refute much that has been written about the unhealthiness or injuriousness of out-door occupations. We, of course, should be the last to deny the evils of the system. At the same time we have no desire to magnify them, nor can we wish to be blind to what may be said in its defence. The writer of these lines has had himself large opportunities of noticing the effects of field labour on women and children, and is convinced that the difficulties of dealing with the system have never yet been thoroughly grasped. It is therefore to be hoped that, as they appear, the reports of the Commission will obtain the attention they deserve.

The Rev. J. Fraser, to whom was entrusted the duty of inspecting portions of Gloucestershire, gives a rather sombre report. In one part he met with a class of people physically and socially a disgrace to that bright county—without schools, in cottages unfit for human habitations, leading almost a wild and savage life, seeming "to lie entirely out of the pale of civilisation." He had never felt so depressed as by seeing on this occasion "type after type of social life almost degraded to the level of barbarism."

The same gentleman, whose report is exceedingly interesting, found, in the course of an extensive inquiry, a general impression against field labour; and that not so much on account of the labour itself as the circumstances that surround such a life.

> "Not only does it almost unsex a woman, in dress, gait, manners, character, making her rough, coarse, clumsy, masculine, but it generates a further very pregnant social mischief, by unfitting or indisposing her for a woman's proper duties at home. Some of the work on which women are frequently employed, such as serving the threshing machine, weeding high wet corn, drawing turnips or mangolds, is work to which, on physical grounds, they never ought to be put at all. Exposure to wet or cold, from which no farm labourer can claim exemption, is likely, owing to the greater susceptibility of the female constitution, to be specially injurious to them."

This is a dark picture, but, we fear, it is too faithful; and it relates not only to the district above alluded to, near Gloucester, but also to parts of Essex, Norfolk, and Suffolk. In Essex and Suffolk we can bear witness, from our own inquiries, to the accuracy of the description.

Fortunately the reports of the Commissioners also reveal a brighter side to the picture. For this we must turn to the North of England, where, also, we have made personal observations that support the more satisfactory report.

Mr. Henley reports on Durham and Northumberland, and his statements are very encouraging. Speaking of certain kinds of work that have been most condemned as unfit for women, he thus writes:—

> "I have always found that such work was not forced upon the women. Their own words are, 'We fight to drive the carts; it is easier work than loading.' They are undoubtedly as fit to be trusted as those of the same sex, in a higher social position and of greater rank, who drive horses in the highest condition in every description of carriage; and with regard to the latter, few would be bold enough to suggest that they do not show as much science and nerve as many men, or to propose legislative interference. It has also been represented to me that such work as turning manure-heaps, filling dung-carts, &c., is unsuitable for women, and the first feeling may be that it is so; but it must be borne in mind that if such labour were not desired by the women and tendered by the farmers, these women would for many weeks be compelled to remain idle in their cottages for want of occupation, to their own and the hinds' loss. There are many who hold the opinion that field work is degrading; but I should be glad if they would visit these women in their own homes after they become wives and mothers. They would be received with a natural courtesy and good manners which would astonish them. Let the visitor ask to see the house; he will be 'taken over' it, with many apologies that he should have seen it not 'redd up.' He will then be offered a chair in front of a large fire, with the never-absent pot and oven, the mistress meanwhile continuing her unceasing family duties, baking, cooking, cleaning, &c. Not one word of complaint will he hear; but he will be told that, though 'working people,' they are not poor; and a glance at the substantial furniture, the ample supply of bacon over his head, the variety of cakes and bread on the board, and the stores of butter, cheese, and meal in the house, will convince him of the fact. When he inquires about the children he will hear that, though they have not much to give them, the parents feel it to be their sacred duty to secure them the best instruction in their power, and '*that* they are determined they shall have.' The visitor will leave that cottage with the conviction that field work has had no degrading effect, but that he has been in the presence of a thoughtful, contented, and unselfish woman. The dress of these north-country women is admirably adapted for their work; being made to fit easily, it does not encumber them, and being of strong materials it defies all weathers. Generally it consists of a pair of stout boots, a very short thick woollen petticoat, warm stockings, a jacket, &c.; over all a washing pinafore with sleeves (called a slip), which preserves their dress from the dirt. Their faces are protected by a shade or 'ugly' of divers colours. Thus equipped they present a great contrast to the draggled appearance of the women who only work in the fields occasionally, wearing some thin gown, with, perhaps, the addition of the husband's coat and boots. Nor is the difference less striking in the results. The occasional worker, not being inured to field labour, frequently suffers from exposure to weather, while the very appearance of the habitual workers is sufficient to prove the healthiness of their mode of life; and the medical evidence is overwhelming as to the absence of disease and of the usual complaints attendant on debility. Dr. Cahill, of Berwick-on-Tweed, states 'from his knowledge of the town and country population' that 'the women of the latter are far more healthy than the women of the former, and tenfold less affected by female complaints.' He considers that their field work fits them to be good bearers of children, and the strength of the population is kept up by them; and that the surplus of the agricultural population that enters the large towns maintains the standard of health and strength by marriage with the inhabitants of towns."

It is further exceedingly gratifying to be told that people thus engaged in toiling in the fields do not neglect the education of their children. Mr. Henley found that these Northumbrian peasants looked upon the education of their children as a sacred duty; that they paid rather high fees for the schools; that the boys and girls, almost without exception, could read and write and do plain figures well enough for their position, and many had an elementary groundwork in geography. Moreover, looking upon education in a wider sense, they had been trained in industry, sobriety, and fidelity, and would therefore, probably, make faithful servants.

This district, too, stands very high for its freedom from crime. Yet there is children's work in these parts, as may be seen from the following extract:—

> "Children seldom, if ever, go to work in the Glendale Union before eleven or twelve years of age, and then merely for summer work. Their employment is herding potatoes and corn, turnip hoeing (two being put to the work of one woman), haymaking, assisting at harvest by making bands, &c., weeding and picking up stones, getting up potatoes, and making straw ropes for thatching. Both boys and girls begin work at the same age, their physical strength at that time being about equal. Horses are never intrusted to the care of boys before the age of fourteen; consequently till that time it is only summer work for which they are required, so that they are able to continue their school attendance during the winter. As the farms are generally provided with cottages for their cultivation, women and children employed upon them have no great distance to go to work, although in exceptional cases when the work lies at the extreme boundary of a large farm, their walk may be somewhat extended. The hours of labour for women and children are nine and a-half hours in summer—viz., from six to six, with two hours and a-half for meals; that is, two hours for dinner, and a short break at nine and at four. In winter the hours are regulated by the light. These hours of work are earlier and longer than in the South. On the

other hand, the women and children are able to return home for a long rest in the hottest time of a summer's day, when they find their dinner cooked for them; and as the majority are single women, the early start from home cannot be prejudicial. I am persuaded that any restriction or interference in the present system of employment of women and children would be detrimental to the social condition of the district, and destructive to the turnip husbandry of Glendale Ward."

Gleanings in Medicine, Surgery, and the Allied Sciences.

MEDICINE.

PYRETHRUM FOR SCABIES.

The *Pacific Med. and Surg. Journal* says:—"Flea Powder" is composed of the flowers and leaves of *Pyrethrum Roseum* and probably of *P. Carnosum*, very finely powdered. It is not commonly fatal to insects, but appears to annoy and stupefy them. If the article be recent and properly prepared, it is decidedly efficacious. When scattered in the track of ants, it is said to drive them away with certainty. A druggist of this city informs us that he keeps his store almost entirely free from flies by dusting it occasionally on the wall and windows, in places where they are accustomed to alight. The insects disappear when they get the powder in contact with their bodies. It is said that when burnt in small quantities in a chamber infected with mosquitoes, it destroys them or drives them away. A tincture of the plant, made with dilute alcohol, is recommended as a cure for scabies. The application is said to give prompt relief from itching.

A NEW TEST IN ALBUMINURIA.

M. Hæbler (*Inaug. Dissert.*, Berlin, 1868) describes a new method for finding the proportion of albumen in urine.

The suspected urine, after having its specific gravity taken, is boiled together with infusion of sugar-cane in a test tube, and then treated with enough acetic acid to precipitate the albumen. The liquid is then filtered, and its specific gravity is again taken when it has reached the same temperature at which it was first taken. Multiply the difference between the two specific gravities (water = 1) by 210 and we have the percentage of albumen present, In thirteen such examinations the average error was only 0·023 per cent., while in Vogel's optical test the average error is 0·046. (*Central blatt für die Medical Wissensch.*, No. 33, 1868.)

SURGERY.

HYPODERMIC MEDICATION IN GOITRE.

Prof. A. Lücke, of Berne, reports in the *Berliner Klin. Wochenschrift*, No. 25, 1868, a very interesting case of this disease cured by the subcutaneous injection of tinct. iodinii fort. (1 : 8). He made the injections at several spots, and at intervals of eight days. He began with four to five drops, and at last got up to two Paraz's syringes full. Until the larger quantities were used, no local or general reaction followed; and only then could iodine be detected in the urine. After four months' treatment, the patient was so far improved that only a few very hard small knots could be felt where the tumours had been.

In the October number for 1867 of the *Archives Générales*, Dr. A. Luton de Oviens publishes the results of a similar treatment; he gives the account of eight cases which were more or less perfectly cured; in one case suppuration occurred.

Luton and Lücke mention two successful cases in which the same treatment was applied for the cure of chronic enlargement of the lymphatic glands.

A NOVEL PRESCRIPTION FOR GUN-SHOT WOUNDS.

About the years 1665 and 1666, Richard Wiseman, who had served in the armies of James I. and Charles II. as surgeon, advocated the following formula for gun-shot injuries: "Boil in two pounds of oil of lilies two new whelped puppies till the flesh fall from their bones; add some earthworms in wine. Then strain, and to the strained liquor add ℥ij. of turpentine, and an ounce of spirit of wine." (*Medical Record.*)

CATHETERIZATION OF THE AIR-PASSAGES IN ASPHYXIA NEONATORUM.

It has often been urged that expiration of mucus and other matters, and the general opening from within outward, or below upward, of the respiratory tract, is the one thing needful in asphyxia of the new born before regular and natural inspiratory movements can go on. On this account, catheterization combined with suction rather than insufflation has often been relied upon in such cases. Dr. Billmann, of Neustadt, relates, in the *Aerztl. Intelligenzblatt*, the case of a new born apparently dead, in which he introduced a thin catheter into the larynx and made forcible suctions. A thick, tenacious, somewhat bloody phlegm passed into the catheter, and immediately a short, deep inspiration took place. After four or five repetitions breathing became gradually established. Aspiration had to be repeated, because phlegm from the smaller and smallest ramifications followed into the larger branches and larynx after the first removal from these. Dr. Billmann admits that electricity may be the most certain means of exciting the contraction of the inspiratory muscles, but urgency and other circumstances of the case often prevent its application. The introduction of the catheter is, however, he says, in itself also a powerful excitant to respiratory movements, and the aspiration of the phlegm and the entrance of the air into the emptied organ are acts so directly stimulating, that it can hardly fail where there is any chance of life left. He strongly condemns the insufflation of air into the mouth; firstly, because the air hardly ever gets into the lungs, and only presses the epiglottis more firmly over the aperture of the larynx; and secondly, because so much air as does get into the lungs only blows the obstructing mucus more firmly into them. In conclusion he warmly recommends the thin elastic catheter not only in cases of foreign bodies in the larynx and bronchial tubes, but as an important means of resuscitation from apparent death generally.

OBSTETRICS.

CASE OF EARLY PREGNANCY.

Dr. Horwitz was called to a pregnant girl who had scarcely reached her twelfth year, and of whose age there could be no doubt. The menses first appeared during her tenth year, and continued regularly. She went through her pregnancy very comfortably. The pelvis was well formed and capacious.

The labour proceeded very favourably, and terminated in ten hours with the birth of a strong living male child. She went on very well, and had a plentiful secretion of milk. References are given to other remarkable cases of the kind on record, (*St. Petersburg Med. Zeitschrift*, 1867. No. 9.)

CONTRIBUTION TO THE ÆTIOLOGY OF VAGINISMUS. BY W. NEFTEL, M.D., NEW YORK.

During the last two years I have had the opportunity of observing three cases of lead-poisoning, particularly interesting by their combination with vaginismus. All three were young women of good social standing, and one of them had been married several years. In all these cases the phenomena of lead-poisoning were so characteristic that I was able to make a correct diagnosis. The patients were unable to lift the hands and fingers, or to abduct the thumb. There was complete paralysis, with atrophy, of the extensor digitorum communis, extensor carpi ulnaris, radialis, pollicis longus, and abductor pollicis; but the supinator muscles, as well as the deltoid, biceps, triceps, and others were normal. The electro-muscular contractility and sensibility were much diminished or entirely lost. The cause of the lead-poisoning in all these cases could be attributed only to the long continued use of a cosmetic containing lead.

But the most remarkable feature in these three cases was the combination of lead-poisoning with vaginismus in its intensest degree; and in consequence of the latter the married lady was sterile, as sexual intercourse was quite impossible. In none of these cases could any particular cause of this hyperæsthesia be detected.

My first two patients were entirely cured by electricity (faradaic and galvanic currents), together with the use of medicines (iodide of potassium sulphur), not only of the paralysis but also of the vaginismus—against which, however, no particular treatment had been directed—and the married lady has since borne a child. I will add, that in the married patient the vaginismus was already developed to the highest degree, while the extensor muscles of the hands were not yet completely paralyzed, but only weakened, and the fore-arms painful.

Accordingly the greatest attention was paid to the condition of the sexual apparatus, which was considered by the attending physicians as the source of the supposed hysterical paralysis. With my present experience, I am inclined to adopt quite a different opinion. I would consider the lead-poisoning as the cause of vaginismus, and the treatment of lead-poisoning sufficient to cure vaginismus, in the same way as it does an analogous condition—saturnine colic.

The third case mentioned was a patient of Dr. Sayre. On the 28th of September last, he kindly invited me, together with Dr. Marion Sims, to see a young lady suffering, as was thought, from obscure disease of the spine, for which she had worn a brace for two years. On hearing the account of the symptoms, I at once stated my conviction that the case was one of lead-palsy, which, on the subsequent examination, was fully confirmed. Here, too, vaginismus accompanied the paralysis of the extensor muscles of the hands.

I bring these few instances before the profession in order that more numerous observations should either confirm my idea of the ætiology of vaginismus, or prove that in my cases the lead-poisoning was an accidental complication. (*Medical Record.*)

ANATOMY AND PHYSIOLOGY.

HYPERTROPHY OF RIGHT HALF OF THE BODY IN A CHILD AGED FOUR YEARS, FIRST NOTICED SHORTLY AFTER BIRTH.

O. B., daughter of Mr. T. B., at present a resident of Brashaw City, aged four years; well grown for age—parents, as well as self, natives of Louisiana; has seven brothers and sisters, all of whom are healthy. The parents are both healthy in every respect; the mother has borne twins three times, the child who is the subject of these notes not being, however, one of the twins.

About ten days after birth, the right half of the person of the infant was found to be larger than the other, and since that time the disproportion has seemed steadily to increase. She is now a strong hearty child; but the disproportion is marked in every particular, more so, however, when the opposite extremities are compared. One leg is about an inch larger than the other, causing a peculiar gait, and the foot requires a shoe of at least one and a half or two sizes larger, and the two arms and hands show a corresponding disproportion. The difference is, of course, not so marked, but can be readily seen, in the head, the eyes, the nose, the tongue, and the trunk all the way down. The only very serious attack of sickness from which the child has ever suffered she experienced in September, 1867, when she was very ill with yellow fever, having had black hæmorrhage by the bowels. I am informed that her recovery from this attack was tedious, and that about ten days after convalescence was considered established, a portion of the alveolar process of the lower left maxillary containing one incisor and a canine tooth, the latter embyonic, sloughed off. Since this she has been restored to her usual good health. Deeming the case a remarkable one, never in fact having heard of a similar, I took a few notes embodying the above facts, and beg leave to report them without comments to the Association. (*New Orleans Journal of Medicine.*)

MAN'S ANTIQUITY IN AMERICA.

At the meeting of the American Association for the Advancement of Science, recently held in the city of Chicago, Colonel Whittlesey maintained that four American races preceded the red man. First, the mound-builders; second, a race in the territory now called Wisconsin; third, a warlike race in the region south of Lake Ontario and Erie; and fourth, a religous people in Mexico. Pottery, arrow-heads, &c., have been found in conjunction with, and beneath, the mastodon and megatherium. A jaw and a tooth were pronounced by Agassiz 10,000 years old. Mr. Foster gave an account of the discovery in a deep gold drift of California of a skeleton covered by five deposits of lava. He exhibited an arrow-head found in the valley at San Joaquin thirty feet below the surface. Human remains have also been found during excavations at New Orleans at a depth of sixteen feet. Mr. Foster exhibited a copper knife found in New Orleans, which he believed was a relict of the mound-builders, and a water jug surmounted by a human head and a statuette of a captive with his hands bound behind him, both from Peru, and evidently of extreme antiquity. The recent explorations of Mr. E. G. Squiers have renewed some old theories as to a connection in origin between the earliest inhabitants of America and those of the Oriental countries. These statements remain, however, as theories only, and do not deserve to be classed with ascertained scientific facts. (*Med. and Surg. Reporter.*)

CASE OF HERMAPHRODISM.

Catherina Hohmann, who presents in her (his ?) own person a remarkable case of hermaphrodisia vera lateralis, which has been described by Prof. Rokitansky and others, is on her travels in Germany exhibiting her unique malformation. She complains, however, that in Vienna the authorities put a stop to her turning an honest penny in this way. So she advertises in the *Wiener Medicinische Wochenschrift* that she can be examined at her own rooms by those interested in her case.

A journalist who saw her, writes to the Vienna *Presse*: "She loved a man for twelve years; he loved her, too, and even proposed to her to go with him to America, where nobody would know of her misfortune; he would live with her and be happy with her. But she refused to accept his generous offer, saying she would not make him unhappy. And then she loved, dreadful to say, for seven months—a young girl. She feels love for both sexes, and does not belong to either. 'What shall I do here on earth?' she exclaimed. 'What am I? In my life an object of scientific experiment, and after my death, an anatomical curiosity!'"

HOW TO PREPARE SECTIONS OF THE BRAIN FOR THE MICROSCOPE.

At the meeting of the Royal Microscopical Society held on the 13th at Kings College, Dr. H. Charlton Bastin read a paper on this subject. Dr. Bastin, who is well known both abroad and at home for his fine researches on the histology of the nervous system, has, we believe, hit upon a method of mounting nerve tissues, which not only occupies but a few moments of time, but is readily adopted by the worker. If this be so, we may soon hope to see a large field of investigation in this hitherto difficult line of histological inquiry. At all events, those who can spare time should attend this meeting and hear the paper. (*Scientific Opinion.*)

Correspondence.

ARMY MEDICAL SCHOOL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Our attention has been called to an article in your impression of the 5th inst., entitled, "Netley and its Expenses."

It is no part of our duty to notice misrepresentations of the kind put forth in that article, but we are unwilling to allow the press to be made the channel for the circulation of statements calculated to mislead the unwary.

A probationary course before entering the service is no novelty in the Medical Department. Before the establishment of the Army Medical School, candidates for Army Medical Service were obliged to do duty at Fort Pitt for a period of time ranging from some weeks to eighteen months, and this, up to the year 1855, *without pay, without quarters, or allowance in lieu of quarters, and this time did not count for service.*

Under the present system at Netley, the probationary course is limited to four months, candidates are supplied with furnished quarters, with fire and light, the attendance of a servant, and five shillings a day. They are made extra members of the Medical Staff Mess, where, we may remark in passing, they learn much that will be of service to them in after years, and their commissions, when they pass into the service, are ante-dated to the time of entering Netley.

In addition to the above, Government provides instruction for them in the specialities of Military Medical Service, which are not, and cannot, be taught in civil schools, and, without a knowledge of which, constituted as the service now is, they cannot perform the duties the State requires at their hands.

All this, you will observe, is very different from the statements made in your article under reply.

We have the honour to be, Sir,
Your obedient servants,
W. C. Maclean, M.D., Deputy Inspector General, Professor of Military Medicine.
Ed. Parkes, M.D., F.R.S., Professor of Hygiene.
William Aitken, M.D. Professor of Pathology.

Royal Victoria Hospital, Netley,
January 12, 1869.

[With every respect to the gentlemen whose names are attached to the foregoing letter, we venture to observe that they have made very small progress towards the correction of the "misrepresentations" of which they complain. We simply expressed our opinion that the medical cadet learned nothing at Netley, which he might not learn with perfect ease and effect after he had joined his regiment, or before he received his gazette, and that it is therefore inexpedient to put him through a medical drill for several months and to keep him on half-pay, which does not nearly meet his daily expenses. Surely, to say that this was done before Netley existed, is no answer to our allegation. *Tant pis*—it only makes Fort Pitt worse, without improving the position of Netley. On one point we accept the connection, and apologise for the error—that the Medical Officer's commission is ante-dated to the period of his passing, and therefore his time at Netley counts as service. We are well aware of the importance of a knowledge of the specialities of Military Medical Service, which, however, would be learned with much better effect in the discharge of regimental duties than in playing at soldiers or learning mess manners at Netley. If Professors Maclean, Parkes, and Aitken desire that we should amend our "misrepresentations," perhaps they will kindly point them out, or, if not, revise their phraseology in favour of a more suitable word.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The accompanying case, taken from my jottings in private practice, may not be uninteresting to the professional readers of your valuable periodical, showing forth the value of the late Dr. O'Farrell's treatment of anthrax, and now offered to the profession:—

Successful Treatment of Anthrax by Strapping.

E. O'M., æt. 40, a driver on the Sligo and Ballina car, applied to me, after his morning drive, with an anthrax on nape of neck about six inches in diameter.

He had been complaining a few days, and no breach being effected, I immediately strapped it from base to apex, leaving about the size of half-a-crown uncovered.

I begged of him to remain under my care in Sligo, but he could not, having no substitute to provide.

He drove thirty Irish miles that day, and during the night tore off the strapping as intolerable, and applied a smoking hot poultice of stirabout, which he repeated several times, until all trace of the anthrax had totally disappeared.

He then went to seaside at Enniscone for a few days and returned to his work, exhibiting himself as having escaped the knife of the surgeon.

About the time of occurrence, I wrote to my son, Mr. James Wm. Johnston, Licentiate of the Royal College of Surgeons in Ireland, with a request that his eminent teacher, Dr. Mapother, would communicate the case with its results.

Now, I am again reminded of the value of the case being made public by my youthful friend and student, Mr. Abm. P. St. Lawrence, whose zeal in the course of science has been meanly instrumental in drawing this out.

James John Johnston, M.R.C.S. England.
Jan., 1869.

THE INTERNAL CAROTID ARTERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Some days ago I had an opportunity of witnessing a very strange anomaly in the course of the internal carotid artery at the dissecting rooms of the Catholic University. It was given off in its usual position from the common trunk about twice its natural size, and arriving within about half an inch of the cranium, it suddenly took a course downwards and forwards for about an inch, and then at an acute angle upwards and inwards assumed its natural course; by this means the external carotid was pushed so far forwards as to obliterate Butcher's space and jeopardise any operation there. The artery on the left side was normal.

Yours faithfully,
J. C. P. Widdup.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Amidst the recent depressing revelations about pauperism, and the clamour of the numerous charities for help, it is pleasant to come across so encouraging a statement as that made by the Melbourne correspondent of the *Times*. From his letter it would seem clear that every able-bodied man might in the colony not only support his family, but put by some of his wages, and thus rapidly rise to a better position.

This is no new statement. It has been made over and over again, and the colonies will continue to cry out for some of our superfluous population. Would not those who have been addicted to impulsive and indiscriminate alms-giving do well to organise some plan by which to send our superfluous labourers where they can command a living? Such an enterprise cannot be more difficult than many that have been undertaken with enthusiasm and the limit of its work would not soon be reached. I am, yours &c.,

Medicus.

THE PROFESSION AND THE PROPOSED REPEAL CLAUSE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—A copy of the annexed letter was posted by myself on the 16th ult. to G. H. Whalley, Esq., M.P. for the City of Peterboro', and which originated from a notice which appeared in the *Morning Star* of December 15, 1868. No reply has hitherto been forwarded to me in behalf of the 20,000 medical practitioners in this country.

I remain, Sir,
Yours faithfully,
M. Redman, M.R.C.S., &c.
Lincoln, Jan. 19, 1869.

Dear Sir,—In to-day's *Star* I observe that you have given notice of a motion to the effect that the House will deem it expedient to repeal the income-tax on trade profit, and the deficiency to be made up by an increase on the property tax.

Am I to understand that this motion is confined to trades, and will not affect professions? If so, I trust you will favourably reconsider your motion, as no profession is more precarious than the medical.

I remember one of our late City members, then a Liberal in politics, Sir Henry (now Lord) Lytton, who advocated a reduction of one-half on incomes derived from professional services. I do not make this communication on behalf of myself, as it is only a secondary consideration with me after a period of twenty-eight years in practice; but for the profession at large I think it is a very important question and an abuse, the repeal of which, like many others, should receive the unanimous assent of both Houses of Parliament.

I remain,
Dear Sir,
Yours faithfully,
G. H. Walley, Esq., M.P. M. Redman.
Lincoln, Dec. 16, 1868.

PEROXIDE OF NITROGEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I observe the following passage in your paper of Dec. 30, 1868:—"Peroxide of Nitrogen.—M. Wurtz supposed that the molecule of peroxide of nitrogen at a low temperature contains $N_2O_4 = 2$ vols., and that it dissociated on heating in two molecules of the body NO_2, occupying 2 vols."

I beg to state that both the discovery that the vapour density of peroxide of nitrogen is about double as great at low temperatures as at high temperatures; and the explanation that there are the two compounds, N_2O_4 and NO_2, are due to Dr. Lyon Playfair and myself. I would refer you to our paper of the year 1861, in the "Transactions of the Royal Society of Edinburgh," and to the "Jahnsbericht" of 1861, p. 25, where you may read what we have done. Our work on this subject has been confirmed by subsequent observers.

Yours, &c.,
J. Alfred Wanklyn, Professor of Chemistry in the London Institution.

NOTICES TO CORRESPONDENTS.

To Correspondents.—We would impress upon our numerous correspondents the necessity of making their lectures, Original Communications' or letters intended for insertion, as short as is consistent with the subject on which they treat. We find it necessary to intimate this to our many friends, in consequence of complaints continually reaching us from contributors, who are anxious to obtain an early publication for their papers.

In deference to the wishes of a large number of our readers, we intend forthwith to devote several columns weekly to *excerpta* from the best British and Foreign journals, in order to keep our subscribers *au courant* with the progress of medicine and surgery in all parts of the world.

Dr. Jacob's "Lecture on the Eye," with illustrations in six colours, is again unavoidably held over till our next.

Dr J. Renton (Gateshead).—Your letter is exceedingly gratifying.

Mater.—The lectures commenced on Wednesday last, at 2·45 p.m. We believe admission can only be obtained by subscription to the course. Annual donations for the support of the College, appear not to entitle the donors to the lecture room.

Dr. Sharkey.—"Dropsy and its Pathology," shall appear as early as possible.

"Chronic Genital Sore," with illustrations, by J. Morgan, F.R.C.S., is unavoidably postponed.

X.—Letter received Its length precludes the possibility of insertion in our present number.

Dr. Edmunds (Female Medical Society).—The matter sent for insertion in our editorial columns cannot possibly appear, *except* in that portion devoted to advertisements.

Dr. Lamprey (Portsmouth)—We will print the two illustrations, omitting the others for the reasons assigned in private note.

Professor Wanklyn.—Your letter in our present issue was unfortunately mislaid by the printer, otherwise it would have appeared on the 6th inst.

Vinctus.—We cannot think that your legal obligation is invalidated by the bad character of your employer. If he had induced you to engage with him under a false representation it would be a different matter, but the law would, we think, hold that you should have satisfied yourself that his professional character was sound before engaging yourself.

J. Duggan, M.D.—"On the Diagnosis of Scarlet Fever;" in an early number.

Dr. J. Luce (Glastonbury).—Will please receive our thanks. The back numbers shall be forwarded as requested. We sincerely hope the interest you appear to take to introduce the journal to your friends will be successful. Prospectuses have been sent.

SHELLEY'S MUSTARD.

(Formerly O'REILLY'S.)

ANDREW H. SHELLEY AND CO., beg to call the attention of the trade and public to this celebrated Brand of Mustard, now being manufactured from this season's superior quality seed. Special attention is devoted to the production of "Best Irish Brown" for blistering and general medical purposes.

Orders Respectfully Solicited.

ANDREW H. SHELLEY AND CO., 55, and 56, Cork-street, Dublin.

MR. HOWARD, Surgeon-Dentist, 52, Fleet-street, has introduced an entirely NEW DESCRIPTION OF ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble the natural teeth as not to be distinguished from the original by the closest observer; they will never change colour or decay, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr. Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed teeth stopped and rendered sound and useful in mastication. —52 Fleet street. At home from 10 till 5.

Fraud. — Caution. — Order BRYANT & MAY'S Patent SAFETY MATCHES, Trade Mark an Ark, and insist upon having them, as imitations are sometimes offered that do not afford PROTECTION FROM FIRE.

A LECTURE ON HEALTH AND DISEASE.

By Thos. C. Shinkwin, M.D.,

Surgeon North Charitable Infirmary, Demonstrator of Anatomy Queen's College, Cork, and Vice-President of the Cork Medical and Chirurgical Society.

Gentlemen,—The older physicians, says a certain author, divided, what is generally understood by the term "Art and Science of Medicine" into three sections; the first comprehended the knowledge of the functions of the body and the organs subservient to those functions; the second embraced those things which, though not part of the living body, are yet essential to its existence; and the third division consisted of an acquaintance with the agents that exercise an influence on disease and health.

It will not be essential for our present purpose to follow out minutely either of these three sections, but where obliged to refer to any function or organ of the living body, we will try and explain its action on the animal economy.

It may appear strange to many when I say that, a departure from a due balance between any of the necessary agencies for our existence will produce disease. Thus, bad cooking will give rise to stomach complaints; inhalation of noxious or foul air will induce diseases of the chest, and frequently of the heart. Unless, therefore, we are acquainted with the action of certain domestic arrangements on the system, some of them producing good, others evil effects, we may give up all hope of leading anything like a healthy life, or, when we become unhealthy of regaining health and strength.

It has often appeared to me strange that though men are so conversant and familiar with nearly all the subjects of what we may call every-day knowledge, that they are so totally ignorant on this subject, which in reality is most essential to the happiness not only of themselves, but of their families and dependents. I hope, however, briefly to clear away some of the difficulties that may lie scattered about the road to sanatory science, and convince you that by carrying out some simple arrangements to which I shall call attention you will confer a great benefit on society at large.

This class of knowledge is undoubtedly much required; for though we have Boards of Health and Sanatory Commissioners to ostensibly see after the health of the people, sad experience tells us that in too many instances their efforts to stir up the community to a right sense of their responsibility have been a failure. It is not my province to discuss the why or the wherefore of this failure on the part of our Boards and Commissioners, but I cannot refrain from expressing it as my belief that were the people given clear and distinct reasons why it was essential to their health to keep their back yards clean, their windows open, and their rooms free from dirt, that we should very soon see a change in their habitations. Tell them the reason one house has fever in it whilst the house a few doors above it has escaped. Try to make them understand that the causes of disease can, by due attention to cleanliness, be held in check. But such a course as this I am advising has never been adopted. An official goes into a man's house and inspects his premises: he there sees filth of the most loathsome description. What has the corporate officer to do? He sends the man in a few days a note to say that unless the state of things be remedied he will be summoned and fined. That moment the man's ideas become antagonistic to cleanliness, and by false reasoning that he will not be deprived of his means of living, he allows himself to be brought before the magistrate for an offence he does not understand; whereas, if he were told quietly that such and such would produce fever, and had explained to him the reason of it, I am almost certain at least comparative cleanliness would be the result. Mind, I am not for one moment laying blame on the corporate officers; they have a most difficult and onerous duty to perform, and they do it to the best of their abilities; but I think if the terrors of the law were withheld, and a milder course adopted, a great deal more good would be the result. Again, we must remember that the dung heap and the filthy yard are not the only causes of disease. How often can we trace some of the severest forms of sickness amongst the poor to want of the essentials of life, want of clothing, want of warmth, and, amongst their children, to the means of caring for their little delicate frames!

The hints that I am about to offer with regard to the preservation of health, and the general sanatory economy of houses must not be by any means looked upon as original. I have consulted many authors on the subject, and though not able to point out what has exactly been taken from each, yet I must candidly acknowledge that their ideas will be pretty freely used in these remarks.

We may lay it down as a truism that there are a great many agencies which cannot only be made subservient to keeping man healthy, but when he becomes ill, can be used as so many remedies to restore him to health. For instance, if a man be a great glutton we can curtail his food; if he takes no exercise we can insist on his doing so; if we are called to see a person with disease of the chest and we find him breathing an impure atmosphere, we can recommend him to try another residence.

Thus, we can use the one agent as a correction of the other. As far back as the days of Hippocrates this system was followed, and with great success, but nowadays, such things will not suit. We are now such a go ahead race, that unless we keep pace with the times, give lots of physic, order our patients a pill every quarter of an hour, and a draught every twenty minutes after; a blister to his chest, and ice to his spine, we shall have the patient's friends deluging him with twenty-four Holloway's pills as a dose, and rubbing three or four pounds of the same gentleman's ointment over his unfortunate body. There are few of us who have not been tired out in watching and waiting for the accomplishment of the process of restoration of the balance of health and strength. We may try many remedial agents, thinking to hasten the cure; each agent tried has in its turn disappointed us; but in that disappointment Nature has often taught its most important lesson, for by the delay we discover how great an ally Nature is and that her laws and her great and varied resources are not to be despised

During sickness, food is too much ignored—and why? Because its value as a therapeutical agent is not properly appreciated by either physician or patient. You may say a certain regimen will not cure disease. I agree with you. Neither will medicine, no matter how skilfully used, but certain condiments will annoy and disturb existing diseases, and then we require medicine to soothe and keep them in check. Would it not be, therefore, much the wisest and more sensible course to adopt in the first instance, to give up the cause and the result will follow? We may, therefore, say that the science of hygienic medicine or sanatory economy is to try and keep the health, and to see that by judicious attention to, and the regulation of, the diet, dress, exercise, atmosphere of dwellings, water-supply, and so on, the working classes are protected from those things that may produce disease. The question might here be asked, Ought the State to interfere in the enforcing compliance with sanatory rules? We say it ought. But in too many instances the State will not interfere, unless disease presents itself in some of its most dangerous and virulent forms; so long as it lurks in holes and corners there will be no notice taken of it, but when it begins to depopulate our country, then—too late to check it—our rulers begin to stir themselves; this is the brief history of all our epidemics.

I have heard it said, "Shame on the men who gave utterance to the sentiment that it was well for a country to be occasionally visited by an epidemic, as by that means the old, the weakly and the decrepid, were carried off from being a burthen on the community!"

It is the principle of life itself, says an author, *which is the care of the State, and that life is as much protected when tenanting a weak and deformed body as when encased in the most herculean figure frame.* As we advance in civilisation, the above sentence becomes more truthful. The existence of a hard and vigorous race in the olden times was absolutely essential to the well-being of the State; but now mere brute force avails but little, the pen wielded by the hand of the puniest body that God ever breathed the breath of life into may change the destiny of a nation, whilst the towering giant rejoicing in his strength and stature may be laid low by the simple sling and stone of the boy David.

As long as people flock together in large numbers in our manufacturing towns, there most surely will disease first make its appearance, and that too amongst the old and worn-out members. In order, therefore, to carry out the principles of sanatory economy or hygienic medicine, you must raise the moral condition of the people, for by so doing you help to dispel many injurious habits of idleness, and dissipate those feelings of sloth which, when left to themselves, engender but too rapidly the many contagious diseases we are called upon to combat.

Original Communications.

ON ABSCESS NEAR THE RECTUM AND FISTULA IN ANO.

By Holmes Coote,
Surgeon to St. Bartholomew's Hospital, &c.

Mr. Samuel Cooper correctly observed that the custom of giving the appellation of fistula to every collection of matter formed near the anus has, by conveying a false notion of them, been productive of bad methods of treatment. To this we may add that to explain away the formation of all abscesses near the rectum on one supposition only, namely, the previous perforation by ulceration of the walls of the bowels, is equally productive of error. Fistulous passages may or may not communicate with the cavity of the intestine, and in the former case the opening may be single, or there may be numerous ulcerated apertures. The fistulous aperture may open externally, or terminate in the areolar tissue around the rectum; the walls of the rectum finally may be in other respects healthy, or be thickened, indurated, and matted together. These points are illustrated in the museum of the hospital (Ser. xvi.). In one specimen we find the fistula extending for two inches upwards on the exterior of the rectum, and then suddenly opening into its cavity. The passage is lined by a smooth membrane, like the mucous membrane of the rectum itself. This is the form of fistula which imperatively demands before operation that the surgeon should find the internal opening, and not force the director through the mucous membrane, be it ever so thin.

In other instances, however, the apertures are numerous. One specimen exhibits a portion of the rectum of which the coats are generally and greatly thickened, indurated, and consolidated with each other and the surrounding parts. Just above the anus there are numerous ulcerated apertures with smooth edges, which lead through the walls of the rectum into short fistulous canals in the surrounding indurated tissue. One canal extends beyond the tissue, through the coats of the bladder, into its cavity. Cases so different are obviously not amenable to the same treatment. A single fistula may extend from the anus upwards, between the fibres of the levator ani muscle, and the longitudinal muscular fibres of the intestines, and not open into the rectum at all, or the fistulæ may be branched. No. 46 exhibits portions of a rectum and the anus; there are irregular and branched fistulous passages, which extend in various directions around the exterior of the rectum, but none of them open into it. They too are lined by soft and smooth membrane.

In a very great number of cases the cause of the disease may be traced to a penetrating ulcer of the rectum, most probably of tuberculous origin. Through this some fæcal matter or gas escapes which excites inflammation, terminating in an abscess. But inattention to the daily evacuation of the bowels, the impaction of hardened fæces and other similar causes, often lead to long continued inflammation, which spreads from the rectum itself to the tissues around. Then the whole mucous membrane may be removed for several inches by ulceration, leaving exposed an irregular shreddy surface, and finally apertures may form leading to short sinuses in the diseased tissues.

In one case the patient, a middle-aged woman, who had long suffered with symptoms of disease of the rectum, suddenly experienced severe pain in the act of defæcation. Death rapidly ensued, when it was found that upon the anterior aspect of the rectum there was an aperture higher up than the rest, which passed through the walls of the rectum, and opened directly into the peritoneal cavity.

In a case under my care, a large collection of matter formed by the side of the rectum after the application of the ligature to a mass of hæmorrhoids. So severe were the symptoms, that the case was considered hopeless by some who saw him. A free incision, however, gave issue to a large quantity of stinking pus, after which the patient slowly recovered.

When the abscess is circumscribed, and does not open by a fistulous passage into the rectum, the pain which it causes is almost unendurable. I lately saw a young married woman the subject of this affection. There was no very visible swelling by the side of the anus, but in one spot the skin was somewhat redder than natural, and a fluctuating swelling could be distinctly felt in the interior of the bowel. A free incision allowed the escape of several ounces of badly smelling pus, and the patient recovered without further symptoms.

It is said that these abscesses present themselves in different forms; thus, one form of abscess, attended by great pain and high fever, is characterised by swelling and induration of the buttock, followed by suppuration in the centre; or, if the redness is more diffused, the inflammation is more superficial, and there is little or no hardness. In other cases the inflammation is of "carbuncular" character, and there is often found a slough of areolar tissue. Sometimes the disease makes its appearance as an induration, close to the verge of the anus. The quantity of matter varies considerably, but the odour is almost always offensive.

In all cases the matter should be evacuated as speedily as possible, the best instrument being a broad double-edged scalpel. The fœtor of the discharge may be corrected by the addition of charcoal to the poultice, or the free use of Condy's fluid. The surgeon has then to wait until the course of events prove whether a fistulous passage will remain after the emptying of the abscess and contraction of the sac.

How should we treat the fistula? In cases where there is no external aperture an operation is rarely required. When the fistula is of the usual length and direction, and the patient's health fair, the employment of the director and the curved bistoury is indicated; but in cases where the patients are delicate and tuberculous disease of the lungs is suspected, I very much prefer the use of the ligature. A long steel probe (armed with a silken thread attached to the side of the probe, which is removable) is introduced into the rectum along the fistula; the point of the probe is then seized by an instrument introduced with the forefinger per anum, and withdrawn, carrying with it one end of the ligature. The two ends of the silk, including the soft parts between the fistula and the anus, are finally tied, but loosely so as to exert no pressure. In three to six weeks the ligature cuts its way out, the wound healing from the bottom. In this operation there is no pain.

In the remaining class of cases, where the rectum is thickened, &c., the use of the bougie is sometimes needed. The bowels should be kept gently loose; and opium in the form of enemata or suppositories to allay pain, and give rest to the diseased parts. But the daily functions of the rectum interfere with the rest necessary for repair, and hence the patient is at a great disadvantage. That this state of things is not free from danger to life, the case reported above will illustrate. No opportunity, therefore, should be lost in impressing on those prone to such disorders the risk which they run, by allowing any false delicacy to interfere with the performance of functions on which the whole bodily health mainly depends.

◆

A CASE OF ENCHONDROMA IN A CHINAMAN CURED BY OPERATION.

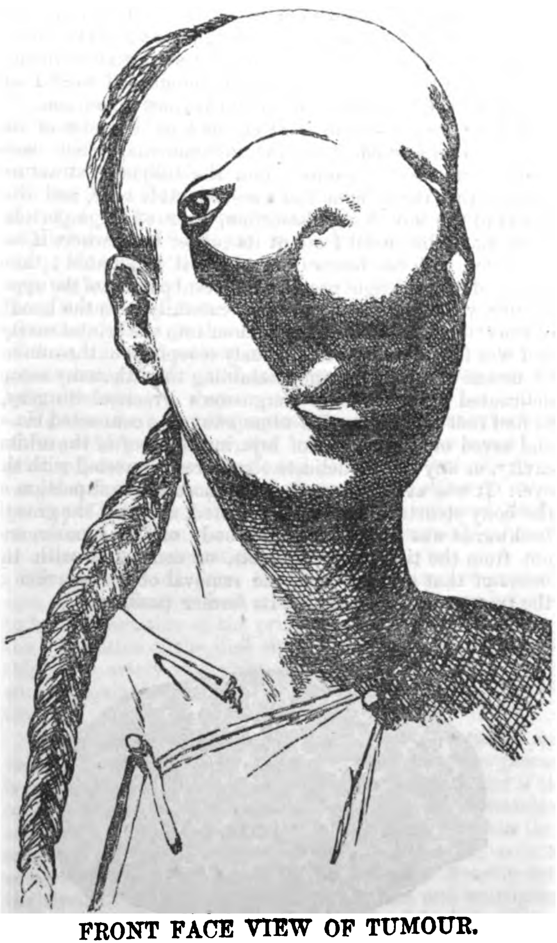
(*Illustrated.*)

By J. Lamprey, M.B.,

Surgeon 67th Regiment.

Among the great variety of cases that came under my notice while in charge of the hospital for native Chinese, instituted by the British Army when in occupation of Tien Tsin, there was none of greater interest, or more satisfactorily showed the utility of the institution, than the case of which the following is a brief record:—

In the month of June, 1861, a Chinaman from the northern part of the province of Chili, entered the hospital, and astonished us not a little by the remarkable size of what at first appeared to be his nose, but which afterwards proved to be an enchondromatous tumour. The subject of it was a tall, healthy-looking young man of the labouring class of the population. His face presented the appearance



FRONT FACE VIEW OF TUMOUR.
(Graphotyped from a photograph.)

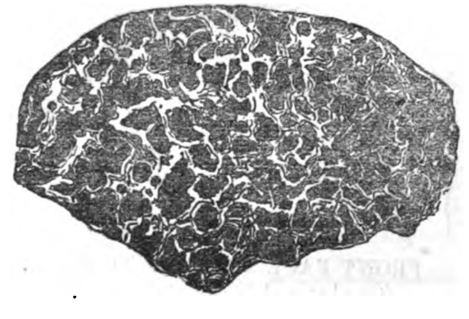
seen in the illustration representing the front view. It was drawn from a photograph done by the photographer attached to the Prussian Embassy, then waiting at Tien Tsin for permission to visit the Imperial Court at Pekin. Through the request of Dr. Lusius, of the Embassy, His Excellency Count Eulenberg kindly gave permission to have the photographs taken, and thus a good illustration of the case has been preserved.

The patient stated that the tumour had commenced to grow about eighteen months previously, and that he did not recollect receiving any hurt to occasion it; that it commenced at the right side of the nose near the inner angle of the eye; that he had no pain in it, and suffered no inconvenience from it beyond its size, which he feared would grow to still greater dimensions and completely obscure his left eye also, as it did do so to some extent. He was willing to submit to any operation for its removal, if this could not be accomplished by medicine. An old cicatrix in the front part of the tumour showed that it had been the subject of medical treatment by Chinese doctors, who had applied some of their escarotics to it. The tumour was globular in form, of irregular outline, and had a firm resisting feel. It was situated between the orbits and in front of the nose, which it concealed and compressed so as almost to close the nares. It extended to the right and left so as to partially overlap the left eye, and to displace the right eye, which projected in front and to the right side fully two inches from its normal position. The eye was quite healthy, and had not lost its power of vision. The eyelids opened and closed at command, and there was considerable mobility of the eyeball. This protrusion of the eye-ball was found to be occasioned by the growth of the tumour into the cavity of the orbit so as to occupy its place.

Seeing how well Chinamen, when in good health, bore surgical operations, it was determined to accede to the man's request to have the tumour removed; accordingly, though the weather was exceedingly hot, I commenced what I anticipated would be a hazardous and tedious operation.

Making an incision in front of the long diameter of the tumour, I dissected back the integuments, which were healthy and easily separated from the subjacent structure. Finding that the tumour had a considerable base, and that it was in the way of my dissection, I cut off large portions of it, bit by bit, until I got at its proper base, where it was connected with the bones from which it originated; these appeared to be the right nasal and adjacent portion of the upper maxillary bones. Feeling my way carefully with the handle of the scalpel, I followed the tumour into the orbital cavity, and was fortunate, while cautiously scooping out the tumour by means of an instrument resembling the lithotomy scoop, delineated by fig. 274 in "Fergusson's Practical Surgery," to find that a large portion came away in a connected mass, and saved me the danger of injuring the roof of the orbital cavity, or any of the delicate structures connected with the eye. It was at once seen that the more internal portion of the bony structure was not implicated, and that the growth backwards was derived from the body of the tumour, and not from the tissues of the orbit, or connected with the bones of that cavity. On the removal of this portion of the tumour the eye resumed its former position.

FIG. 2.



The bones (right nasal and adjacent portion of the upper maxilla) forming the base of attachment of the tumour, were softened to a considerable extent, and showed a gradation into the fibro-cartilaginous structures of it; all this diseased structure was removed, as far as possible, before the integuments were brought together and the ordinary sutures were applied. There was not much hæmorrhage, even when the tumour itself was cut into, although highly vascular as regards its internal structure, at least the hæmorrhage was no impediment to the operator.

Fig. 2 shows the appearance presented by a section of the tumour. It is intended to represent the fibro-cartilaginous granular bands traversing the tumour in all directions, and the vascular structure filling up the interspaces. This appearance, together with the intimate connection with the bony base, indicated its origin to be connected with altered bone structure.

On the day following the operation much inflammatory action was apparent, and warm poultices were applied, instead of the cold water applications; considerable fever ensued and continued for some days, and large discharges of very fœtid pus came away from the wound. I was not disappointed at this, but rather considered it to be a favourable occurrence, as Nature was no doubt removing any traces of diseased structure that might have escaped the knife.

The appearance of this man after the wound had healed, and before he left the hospital in August following was satisfactory. In the month of December following, this man again presented himself at the hospital, when his appearance was still more improved, and there were no indications of renewed growth of the tumour, and the eye which had been so long displaced completely recovered its normal position and mobility.

Enchondroma is not an uncommon disease among the Chinese. On another occasion I removed a very large tumour of this peculiar growth from the hand of a Chinaman by amputating the finger on which it grew, and restored the use of the hand, which otherwise would have been an incumbrance, and rendered the upper extremity useless to him, as the operation was quite beyond the skill of the Chinese, who were hitherto ignorant that diseases could be so radically cured.

Hospital Reports.

REPORT OF CLINICAL LECTURES

DELIVERED AT

ST. GEORGE'S HOSPITAL.

By Mr. Henry Lee.

CASES OF MORTIFICATION CONNECTED WITH DISEASE OF THE ARTERIES.

Case I.—M. D., æt. fifty, was admitted 24th July, 1867, into St. George's Hospital, under the care of Dr. Ogle. There was then a tumour on the right side of the navel, which had existed, as far as she knew, two months. On the 6th August, the toes of the right foot became affected with gangrene. There was a good deal of pain in the ankle and toes. There was then no œdema.

In the beginning of October a fresh swelling appeared in the left inguinal region, and in a few days the left leg became œdematous. I was now requested to see her in consultation with Dr. Ogle, and concluded that, as the gangrene had occurred on the opposite side to the swelling, it depended on some disease of the arteries, and not upon obstruction to the veins.

The patient died on the 29th of October. Upon a *post-mortem* examination, the liver and kidneys were found fatty. In the right iliac region was a large hard firm mass, about the size of a fœtal head, which lay somewhat obliquely across the abdomen, resting on the right iliac artery just after its bifurcation. It was found to be a cancerous mass, hollow, and full of fæces. In the left iliac fossa was a similar malignant deposit, the size of an egg, and closely adherent to the bone. The inguinal glands on this side were likewise enlarged, and one gland, the size of a walnut, pressed upon the femoral vessels as they passed under Poupart's ligament. The deposit in these glands was of the same nature as in the tumour on the right side of the abdomen. The aorta was in several places much diseased; large deposits of atheroma, as big as a sixpenny-piece, were found all over its surface. On the lining membrane were some oval-flattened masses the size of large peas. Some portions of these were of a dark red, others of a bright red colour; and one lay completely detached. There was no trace of inflammation of the lining-membrane of the vessel. The right popliteal artery contained a long decolourised mass of fibrin, in which two of these red masses were embedded. This fibrin adhered firmly to the vessel at one part by a broad membranous band. The canal of the artery was, however, pervious. All the veins in the left lower extremity were full of decolourised clots, which were adherent. The posterior tibial veins on the right side were also plugged. The nature of the oval masses found in the interior of the vessel formed the chief point of interest in the case. They all presented a shining lubricated exterior, and adhered, with one exception, tolerably firmly to the coats of the vessel. A delicate membrane, apparently continuous with the lining membrane of the artery, could be traced to a greater or less extent over their surfaces. Upon a microscopic examination, these masses were found to consist of blood and altered fibrin, and of fatty matter.

Case II.—C. D., æt. fifty-five, was admitted into St. George's Hospital under my care on the 5th December, 1866. He had at that time a sloughing ulcer, about three inches in extent, nearly surrounding the lower part of the right leg. He attributed the ulcer to a bruise which he had had a month previously. The patient was depressed, with a full, weak pulse, which sometimes intermitted. The cause of his depression was carefully looked for, but no evident sign of disease of any of the internal viscera was detected. With slight variation, the ulceration continued and exposed a portion of the tibia; and the patient died on the 2nd of January, 1867.

Upon a *post-mortem* examination, the body was very fat. The lungs were much congested. The heart was very large, weighing twenty-four ounces. The valves were very atheromatous, and quite rigid. The aorta was covered with patches of atheroma the size of a threepenny-piece; some of these patches were softened and broken down in their centres. Where this had taken place, ulcers with ragged edges were left surrounded by congestion. The liver was congested and fatty; the spleen diffluent, and its structure broken down. The kidneys were large and coarse, and their structure rotten. The arteries of the right limb were examined, and found to be rigid, and considerably changed by atheroma. Small shreds of fibrin, more or less firmly attached, were found on the surface of the ulcers in the aorta.

In the course of two clinical lectures on the cases we have quoted, Mr. Lee considered the process of repair that is instituted when an artery is injured, and pointed out that this process is conducted by means of a material deposited from the blood, closely allied in its nature to ordinary fibrin. In this adventitious substance may be seen under the microscope, as has been so well illustrated by Dr. Beale, a number of granular cells undergoing subdivision and multiplication. These cells in their characters resemble the white corpuscles of the blood, and cannot, in fact, be distinguished from them. He then showed that the material thus deposited in the healthy process of repair became organised, but that if it did not become organised (except in cases of aneurisms), it was removed in the current of the blood. He afterwards considered some of the effects which may be thus produced, showing that the two processes, which can be traced in the repair of blood-vessels, bear an analogy to similar actions which are more easily observed on the surface of the body. The material effused between the cut edges of a wound of the skin may be completely organised, so as to remain a part of the living tissue; or, on the other hand, it may be thrown off as unorganisable matter. In the latter case the quantity of new material generated is very much greater than in the former. The matter thus formed by the multiplication of cells on the surface of the body, and not organised, is thrown off in the process of suppuration; but the products of any analogous actions in diseases of the vessels are liable to be poured into their cavities. If the process of repair in an artery is accomplished by the first intention, only so much new material is deposited as may be requisite; but if the repair by the first intention be not accomplished, then other actions take place which may lead to the obstruction, more or less complete, of the vessel. The morbid products may then mix with the blood, which has a tendency to carry them in the course of the circulation. The quantity of material thus formed, either by the subdivision and multiplication of adherent cells, or by the direct deposit of fibrin from the blood, is often very great; so that the cavities of the largest as well as of the smallest vessels may become closed by this means for many inches.

Cases in which veins are obstructed in this way are of constant occurrence; but the instances in which arteries are similarly affected are more rare. When any matter is thus deposited in a diseased vein, and does not remain adherent, either directly or indirectly, to the sides of the vessel, we look for the results of its being carried along in the course of the circulation: when an artery is thus affected, we look for results in the parts to which the ultimate subdivisions of the artery are distributed. It does not, however, often happen that the cavity of an artery becomes obstructed by the fibrin-like material above mentioned, independent of other disease. In wounds of arteries which do not unite by first intention, if a large quantity of this material is deposited, it is not generally in the interior of the vessel. Usually an aneurism forms, and the fibrin then is deposited outside the vascular system. Mr. Lee believes, however, that there is a class of cases which has not hitherto attracted much attention, in which the products of other diseased actions may find their way into the interior of arteries. The changes in the arterial coats themselves have been accurately described; but the secondary effects produced by the entrance of the products of these diseased actions into the circulation have not been satisfactorily traced, and to these Mr. Lee's attention has been directed.

He remarked that Dupuytren believed that spontaneous, senile, or dry gangrene was due to inflammation of the principal arteries of the affected part; and that the blood coagulated in the cavities of these vessels, either in consequence of its being in contact with the inflamed lining-membrane, or from its admixture with coagulable lymph, or as a result of ulceration of the internal coats.

He next quoted from Sir Benjamin Brodie's works a case of mortification from what that great surgeon believed to be inflammation of the principal vessels of a limb: from the bifurcation of the iliac trunk down to the middle of the thigh the artery was obliterated, being completely filled with coagulable lymph, evidently effused from inflammation.

If Mr. Lee's account of the mode in which arteries and veins ordinarily become obstructed be correct, the process is not necessarily connected with inflammation; and if the coats of the vessels are at all inflamed, it is as a secondary consequence of actions which occur previously within their cavities. The matter which obstructs the vessels is in no sense a secretion, but is formed by a deposit directly from the circulating fluid, or by the subdivision and multiplication of cells resembling the white corpuscles of the blood, and of matter formed by these cells. In chronic states of disease the changes observed in the coats of arteries consist chiefly of steatomatous or atheromatous deposits. These deposits are liable to become softened, and when the lining membrane of the vessels gives way, this softened material is poured into the current of the circulation. The blood in a diseased artery then becomes mixed with a material (in process of degeneration) really derived from the arterial tissues.

Lebert describes the pultaceous softening of atheromatous disease of arteries on microscopic examination as of a yellowish-white colour, containing molecular granules, vesicles, granules of fat, crystals of cholesterine, calcareous granules, and *débris* of the elements of the middle coat.—(*Anatomie Pathologique*, p. 513.)

That fatty matters will not readily pass in the current of the circulation, has been shown by experiment. Majendie states, in his *Précis Elémentaire de Physiologie*, that some fluids pass readily from the arteries into the veins, but others are obstructed in their passage. Clear solutions of tartar emetic, of opium, or of nux vomica, as shown by Gaspard, pass readily in that way, and little or no irritation is produced in the vessels through which they are conveyed. But other substances, such as the infusion of tobacco, the solution of acetate of lead, or putrid fluids, when injected into the artery of a limb do not readily pass through the capillaries; and then the local irritation is great. That which may be thus illustrated by physiological experiments, may occasionally be observed in practice. In Case I. (MEDICAL PRESS AND CIRCULAR, Dec. 9th) the diseased products from the internal coats lodged in the large arteries in which it was formed, in arteries of intermediate size, and in the capillaries. In Case II. it lodged in the capillaries only.

It has been generally, and perhaps too hastily, assumed that mortification in cases where the arteries are diseased depends upon the want of a sufficient supply of blood to the part. In Case I. the circulation was partially arrested by adherent coagula in the aorta; the popliteal artery was all but impervious; and the circulation completely arrested in the distal portion of the limb. But do the facts justify the inference that mortification took place from want of blood? In cases where the supply of blood is suddenly arrested the part becomes pale and cold. The very reverse of this is generally observed in cases of mortification in connection with disease of the arteries. In corroboration of this statement, Mr. Lee cited a case related by Mr. Turner in the "Transactions of the Medico-Chirurgical Society of Edinburgh," in which the circulation in the forearm was arrested in consequence of an accident: "The forearm was pale, and the veins much smaller and more collapsed than those in the other arm; and when they were compressed they filled slowly." Also a case related by Mr. Chevalier in the "Medico-Chirurgical Transactions," in which a gentleman received a very severe blow from the shaft of a van in the left groin. This was followed by great pain in the leg and foot. The day following he had lost all sensation in the lower half of his leg. There was no pulsation in the arteries of the injured limb, the skin of which was "pale and cadaverous." After some time the ankle and foot assumed a deep transparent colour not unlike that of new mahogany. This did not disappear upon pressure. The toes were dried and shrunk; they were paler than the ankle, and their substance was transparent; they resembled parts dried and immersed in turpentine. The cuticle did not separate. The temperature of the right toes in this case was 90°, that of the left toes varied from 66° to 71°. On a *post-mortem* examination the arteries were all found to be impervious in the neighbourhood of the original injury. In a case that occurred to Mr. J. A. Gamgee, a woman, eighty-five years of age, suffered from gangrene of the foot, which had never been black, but was of a dirty-white colour. The popliteal artery of the corresponding side was found obliterated by a firm, adherent, whitish clot. The anterior and posterior tibial arteries were also closed by white adherent clots.

Mr. Lee pointed out how, in contrast with the abovementioned cases, the appearances presented by the great majority of those in which mortification has taken place in connection with disease of the arteries show that the affected parts have contained much more blood than natural. The blood has stagnated in the capillary vessels, and has been altered in colour and consistence. It has been defective in quality, and not in quantity. That such is the case, and that the quantity of the blood alone, independent of disease of the arteries, may produce mortification, is further illustrated by the case of a patient admitted under Mr. Lee into St. George's Hospital, with a child that she was suckling. She had an attack of erysipelas. The child then for the first time became poorly, and the skin of the whole of the toes, and of a large part of the foot, mortified. The toes separated naturally, and the wound healed. The child afterwards continued in perfect health. In practice we see that the circulation through the arteries may be impeded by the formation of coagula in their channels, or the return of blood through the veins may be retarded by local pressure, and the quality of the blood may be altered at the same time. These influences may have some effect in the production of mortification, and may have been in operation in Case I. But the alteration in the constitution of the blood, and the consequences of that alteration, is that which Mr. Lee thinks the most frequent cause of mortification. In Case I. there were portions of blood coagulated in contact with the diseased lining membrane of the aorta. These coagula were covered with a shining membrane, and adhered to the aorta. Considering the force of the circulation through the vessel, he could come to no other conclusion than that they were formed *in situ;* and being formed upon the diseased lining membrane, or where that membrane was deficient, it was highly probable that they contained some of the products of the diseased actions which had taken place. Those diseased products may indeed have been the efficient cause of the coagulation of these portions of blood. At all events, the existence of these coagula, as they were found, proved that coagulation of blood may take place in living vessels, and that the coagula thus formed may have a firm adhesion to the sides of the vessel or may be independent of them. The tendency to coagulate must have been very powerful where the effect could be produced under so many disadvantages as in the aorta. It was not, therefore, surprising that this tendency should produce a greater result in more favourable situations. Accordingly, where the arterial tubes were smaller, where the impulse of the blood was less, where the artery subdivided into several branches, much larger coagula were formed. When these several conditions were present in a great degree many vessels were obstructed instead of one, and the circulation of the part completely arrested.

In Case I. the coagula in the aorta were covered with a thin lubricated shining membrane. The mode of formation of such membranes upon clots in blood-vessels appears strictly analogous to the process which Mr. Hewett first described.

Further, independently of the obstruction of the circulation by coagula, there are other circumstances with regard to the blood which tend to prevent its passage through the smaller capillaries. Thus fatty matters, as has been shown, pass through the capillaries with difficulty, causing pain and swelling. The products of the degeneration of the coats of arteries are chiefly fatty, and when these mix with the blood, we have the conditions presented so frequently in a senile gangrene.

When cell-growth takes place in portions of fibrin deposited on the lining membrane of an artery, that growth may continue for a certain time quite independent of any action in the membrane with which it is in contact; and when the material in which such cell-growth has commenced is detached from its original position, that growth may still continue in the distant parts to which the material containing these cells is transferred.

Pain, swelling, softening of parts, and mortification may be produced by diseases originating in the vessels which supply a limb, and at a distance from the part where the effects of those diseases first manifested themselves. It is very difficult to prove in any individual case that such a translation of disease has occurred, because it is manifestly impossible to examine the parts both before and after its occurrence; but where such evident results present themselves as in the cases recorded, it must necessarily happen that less severe affections should occasionally occur.

Mr. Lee said that the mildest form of disease which he had witnessed, and which he considered of this nature, resembled a very painful soft corn. The cuticle over the part became ragged, and when removed the cutis showed several small black spots. The disease occurred in a part not subject to pressure, and continued several days without alleviation of the pain or tenderness. He noted it particularly on two occasions, and both times it presented itself in young people on the bulbous extremity of the little toe.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE Society held the second meeting of session 1868-69 on Friday evening, January 8, in the Albert Hall, Royal College of Surgeons.

The President of the College, Mr. PORTER, in the Chair.

Members present.—Messrs. Wharton, Jameson, Labatt, L'Estrange, C. Benson, B. Wills Richardson, Mapother, Macnamara (V.-P.), Morgan, W. Moore, H. G. Croly, Wm. Stokes, jun., P. White, H. Kennedy, H. L. Stoney, Roe, Stoker, F. Kirkpatick, J. R. Kirkpatrick, Stewart, Kelly, M'Dowell, Athill, Brassington, Denham, Murdocke, Coulton, Fletcher, Purcell, Martin, O'Leary, C. Fleming, Brady, Owens, E. Hamilton, Usher, Booth, D. B. Hewitt, Hewitt, jun., Little, O'Grady, Barton, Tuffnell, Montgomery.

TUMOUR OF HAND.

Professor MACNAMARA said, that in bringing the specimen before the Society, he wished in the first place to offer his most earnest thanks to his friend, Dr. Thomas Pratt, for sending the patient up to him. He could not say how much he thought an example such as that should be followed by their provincial brethren; and he hoped, therefore, that they would imitate the example of Dr. Pratt by sending up remarkable cases which might come under their notice, for the information and improvement of our metropolitan students. Never, in the course of twenty-five years' practice, had he (Professor Macnamara) seen a specimen of such magnitude as that which he now presented to the Society, and he believed the President had never met so large a one in his practice. The subject of it was a boy thirteen years of age, in every other respect, healthy. He was admitted to hospital on the 23rd of December with this enormous tumour of the hand. There was some question as to whether the growth was congenital or the result of a burn. When about two years of age, the boy fell into the fire and burned his fingers, but whether that could have resulted in this disease he was not prepared to say. He (Professor Macnamara) presented the tumour, as well as a cast, which exactly represented it. The tumour was solid in every part save one, in which it had commenced to ulcerate. It implicated the second and third fingers, and, so far as he could make out, did not engage the metacarpal bones. There could be no question but that there was only one plan of treatment to be adopted—namely, the excision of the whole mass. He considered, however, that the fourth finger, the index finger, and the thumb might be saved. With respect to the condition of the bones of the forearm he might state that the radius was arched exceedingly and that to some observers the ulna might seem to be totally absent. On careful examination he thought he could trace a rudimentary ulna at the wrist, becoming more evident towards the elbow-joint. They would readily see that the boy, carrying this large weight, the thumb upwards, the ulna in a position between pronation and supination, pressure upon the epiphysery process of the ulna took place and arrested its development; the great weight tended also to arch the radius. He was vain enough to think that he should be able to give the ulna and the radius their proper position. As to the operation, he might briefly say that it consisted in making a quadrilateral incision, dissecting a dorsal flap back, disarticulating two or three fingers, dissecting the growth forwards, and forming another flap from the palmar aspect of the hand. He was happy to say the case was going on in a satisfactory manner. The boy will have the fourth finger, the index finger, and the thumb, with the palmar aspect of the hand. It might be said that by making an incision of a triangular form, and taking out the metacarpal bones there would be a more useful hand. He could not accept that view, for the boy had to earn his bread by the labour of his hands, and therefore the larger the palmar aspect of his hand the better. He was happy to say, from the appearance of the boy's palm when he dressed him that morning, that he would have a hand as well able to work a spade as if this disease had not occurred. Professor Macnamara then pointed out a specimen of a remarkable case of a similar nature which had been under Mr. O'Beirne's care, and in which, as contrasted with the present, a large portion of the palm had been removed. He had only further to say that the tumour on removal weighed 1¼lb., and would repeat that this great weight, placed in the position he had described, would account for the apparent non-development of the ulna and the arched condition of the radius.

SYPHILITIC SLOUGHING OF PHARYNX—GANGRENE OF NOSE.

Mr. MORGAN exhibited a specimen showing extensive sloughing of the back of the pharynx, gangrene of the nose, and an atrophied heart, from a syphilitic case. There was no valvular disease, but that peculiar form of atrophy of the heart which was so often seen in syphilitic cases. The subject of this disease was a woman, thirty-four years of age, who had been admitted to the Lock Hospital on the 17th of November, and who died on the 4th of January. On the 24th of December the symptom indicative of approaching death—gangrene of the nose—first set in. A spot about the size of a sixpenny piece made its appearance on the end of the nose, gradually extending round the bridge of the nose, and before she died the discolouration had almost reached the eyes and nearly as low down as the under lip. She said that she had been for ten years living an irregular life, seven of which she had passed with one person, and for the last three years she had been on the streets. Three months only before she came into hospital she got a simple sore on the pudendum, not accompanied by bubo, nor having any of the characters of a soft sore. There was no evidence on the body of any secondary symptoms. He could, however, see a slough on the back of the pharynx, and that a small portion of the soft palate had been eaten away. After death he found that the slough extended from the occipital bone all along the back of the fauces, having destroyed the soft palate down to the larynx, and necrosed a portion of the os hyoides and extended into the larynx down to the thyroid and arytenoid cartilages. The heart was of small size, weighing only six ounces, and was partially atrophied. There were the ante-mortem clots, a clot in the pulmonary artery, and one in the aorta. The substance of the ventricle was of normal consistence. There was nothing peculiarly observable in the liver and lungs; but on examining the uterus he found a small deposit in the fundus. Syphilitic depositions had probably taken place in the uterus, but this was so like the fibrous tumours so often found in the uterus that he would not speak more positively about it. The amount of sloughing which this case exhibited was unusual. For the first three days the action of carbolic acid seemed to arrest it, but as debility set in, the sloughing extended itself with great rapidity. Mr. Morgan exhibited a lithographic drawing showing the appearance of the woman's face before death.

Mr. WILLIAM STOKES read the following paper:

TRAUMATIC FRACTURES OF THE LARYNX.

ON September 22nd I was summoned to the Richmond Hospital to perform tracheotomy on a female, who had just been admitted, suffering from extreme dyspnœa, which had come on rapidly after receiving a kick in the throat from her husband. The account that was obtained from the patient's friends was, that she had a dispute with her husband relative to some money which she had about her, and of which the husband wished to get possession. All persuasion to obtain it from her failing, he had recourse to violence, and threw her down on the floor. On attempting to rise he kicked her on the throat, which had the effect of again prostrating her. I presume that some symptom she had then alarmed him, for he offered her no further violence, and she shortly after rose and stated that she would charge him for this brutal assault. While in the street looking for a policeman, and experiencing probably the usual difficulty in finding one when he is required, the dyspnœa commenced. It rapidly increased in intensity, and she was immediately brought to the Richmond Hospital. On her admission she was almost inarticulate; there was a cold sweat on her forehead; her pulse slow and weak; her face much flushed, and her lips livid. Her respiration was laboured and difficult, but not so much as to make those about her think, that the case was about to terminate so suddenly as it did. I was immediately summoned, and lost no time in getting to the hospital; but on my arrival I learned that the patient had just expired. I found considerable flattening and abnormal breadth of the throat. There was no apparent ecchymosis, but much effusion and infiltration among the soft structures were distinctly felt. From these appearances, as well as from the abnormal mobility of her laryngeal cartilages, and also an obscure crepitation, the diagnosis of fracture, with displacement of one or more of the cartilages of the larynx, was made—a diagnosis which the *post-mortem* examination verified. All the soft tissues about the larynx were found profusely infiltrated with blood, although no laceration of a large vessel could be determined; it was more copious and extended further back on the right side than on the left. On taking out the larynx I found that there was a double fracture of the cricoid cartilage. These two fractures were symmetrical, each being situated at about half a quarter of an inch from the middle line. There was displacement backwards and slightly inwards of the left fragment, separation of its articulation with the inferior cornu of the thyroid, and considerable laceration of the crico-thyroid muscle on that side. The displacement of the fractured portion of the cricoid was not observed on the right side. Here, posterior and external to the thyroid and cricoid cartilages, and by the side of the epiglottis, there was a considerable effusion of blood, of itself contributing in no small degree, by its pressure from without, to the closure of the larynx. The obstruction, however, was chiefly caused by the effusion of blood beneath the mucous membrane of the larynx, especially under the aryteno-epiglottidean folds and in the ventricles of the larynx, which produced almost complete occlusion of the glottis, and consequent apnœa. There was no laceration of the mucous membrane, and consequently no emphysema.

The occlusion, therefore, was caused by the existence of the four following conditions:—

1. Effusion of blood external to the larynx.
2. Effusion under the lining membrane causing closure of the glottis.
3. Displacement inwards of right fragment of cricoid.
4. Displacement of arytenoid on right side.

In this case, therefore, we had an injury of the larynx which, as far as I can determine, is unique in its character, viz., a multiple or comminuted fracture of the cricoid, and also a double displacement, one of a fracture of the cricoid, and the other of the right arytenoid.

It is very remarkable how few recorded cases of traumatic laryngeal fractures are to be found in surgical literature. M. Cavasse, in whose valuable memoir on laryngeal fractures will be found an exhaustive account of the different characteristic signs of these injuries, gives—excluding the cases of fracture of the larynx produced by hanging and those of the os hyoides—the particulars of only nine cases. In one of these the fracture involved the cricoid, thyroid, and arytenoid on one side; in two others the thyroid and cricoid were fractured; and in the remaining six the thyroid alone. It would appear, therefore, that the case which came under my observation differed from these in this, that the cricoid cartilage alone was fractured.

We may classify the signs of these injuries into the functional and physical. Among the former continuous dyspnœa constituted, in seven out of the nine recorded cases, a characteristic symptom; in this case it was extreme, so that in eight out of the ten cases it was present. In the two cases in which it was not present, which were recorded respectively by MM. Picdagnol and Marjolin, there was no dyspnœa; and it is remarkable that in these two cases the form which produced the lesion was applied on the side of the larynx, and not immediately in front of it. It is hard to say if this circumstance was accidental or not, but it was one which might possibly be of some importance in a medico-legal point of view. The causes of the dyspnœa are—first, sub-mucous effusion of blood; secondly, effusion of blood external to the larynx; thirdly, displacement of the cartilages; fourthly, deformity of the glottis; and lastly, abnormal mobility of the point of attachment of the vocal cords. These are mentioned by M. Cavasse, with the exception of the second, the effusion external to the larynx, which was so well marked in the case which fell under my observation. It was so extensive as to partially displace the larynx to one side.

The second important sign is facial lividity as indicating an impeded respiration.

Another frequent, but not invariable, symptom is alteration in the voice. Sometimes there is complete aphonia, as in the case which came under my observation. In other cases the voice was hardly affected. There is, therefore, great difference in the intensity of this sign which appears to be due to the varying etiological conditions producing these lesions, and also to the mechanism of them. From the recorded cases it seems that the fractures produced by lateral pressure are less liable to be accompanied by aphonia than those produced by force applied directly in front. This is, in truth, what we would expect, as injury to the vocal cords or their points of attachment would not be as likely to follow after the direct application of lateral force, as, in this case, the resistance is so much less than when it is applied directly in front.

The remaining functional sign of these injuries is pain, which also is not invariable, but in some cases is extreme, and may be either spontaneous or be induced by manipulation, by attempts to speak, or by the act of swallowing.

The physical signs of these injuries are—

1. Alteration in form of the neck.
2. Increase of volume of the neck.
3. Abnormal mobility of the cartilages.
4. Ecchymosis.
5. Crepitation.
6. Emphysema (rare).

The principal alteration in the form of the neck is flattening anteriorly, produced by the obliteration of the pomum Adami in cases—namely, when the force is applied from before backwards. M. Cavasse observes that as yet no one has noticed the change in the form of the neck when the fracture is produced by lateral pressure. The flattening in cases of fracture produced by antero-posterior pressure appears to him to be more marked when the cartilages are ossified. When they are not, the elasticity of the cartilages ought to restore the larynx to its normal form. There are two ways of establishing abnormal mobility—first, by making lateral pressure there is little resistance found in approaching the cartilages of the larynx; and secondly, in passing the fingers down the mesial line a vertical depression is easily perceived. This latter manœuvre indicates much better than the first the situation and direction of the fracture.

There are in these cases two situations for the ecchymosis. One is subcutaneous, and acts chiefly in producing alteration in form and increase in volume of the neck; the other is deep in the immediate vicinity of the lesion, and may, if very extensive, assist in no small degree in producing dyspnœa by pressure on the windpipe. These two hæmorrhagic effusions never communicate, being prevented from doing so by the cervical layers of fascia.

Another physical sign of great moment is crepitation, which, however, is more often absent than present. Its absence may be due to many causes, among which may be mentioned the fracture being incomplete, the cartilages not being ossified, and also it may be impossible to produce it in consequence of the extensive hæmorrhagic effusion immediately external to the fracture. This must necessarily produce considerable difficulty in moving separately the fractured portion of the cartilage or cartilages.

The last physical sign I would mention is emphysema, which is extremely rare. It did not occur in my case, and in only one of those recorded by M. Cavasse. It was a case which was under the care of M. Langier, one of the surgeons of the Hôtel Dieu. The fracture occurred from a fall down a flight of stairs. The patient was a man aged 48, and was admitted into the Hôtel Dieu on November 20, 1858. Immediately after the accident (9 a.m.) there was considerable oppression of breathing, and at 2·30 a.m. the following morning he walked to hospital. His gait was slow; head thrown slightly backwards; face anxious; mouth open; face pale; lips cyanotic; body covered with a cold sweat; pulse frequent and feeble; respiration stertorous and blowing; considerable aphonia. The oppression increased on the slightest effort to speak. He would not remain in hospital, but six hours after returned with a marked aggravation of all his previous symptoms, and, in addition, the existence of a deep-seated emphysema was easily determined. Shortly after this the patient died suddenly. The *post-mortem* revealed a vertical fracture of an ossified thyroid cartilage; extensive hæmorrhagic effusion; laceration of crico-thyroid membrane; vertical and dentated fracture on right side of cricoid cartilage; fracture of right superior corner of thyroid cartilage; laceration of ligaments of right crico-thyroid articulation; fracture of great corner on right side of os hyoides; *luxation of* arytenoid. and *laceration of mucous membrane;* ecchymotic effusion in sub-mucous cellular tissue.

The only other case that I will allude to, and that very briefly, is the case which was under M. Maisonneuve's care in the Hôpital de la Pitié, May 10th, 1857. The patient was a young man, aged 24, by occupation a mason, who was thrown down by a dairyman's cart, one of the wheels of which crushed the larynx in passing over the anterior portion of the neck. On his admission he was in a state of semi-apnœa, with all the other usual signs and symptoms of an impeded respiration. Apnœa was warded off by a venesection, but its good effects did not last; a second was performed, and a third the day after. On the fifth day the dyspnœa became so urgent that tracheotomy was performed. The operation, owing to the crushed and flattened condition of the larynx, and the neighbouring soft parts being swollen and contused, was accomplished with extreme difficulty. The case did very well; but the patient, owing to contraction of the larynx, which became permanent, was obliged ever afterwards to wear a tracheotomy tube.

The successful result of tracheotomy, which was obtained in this remarkable case of M. Maisonneuve, makes it a source of unceasing regret to me that I did not arrive at the hospital sufficiently early to perform the operation, and in all probability save the life of the patient whose case is the theme of this communication.

Dr. O'Leary asked Mr. Stokes whether he thought the effusion of blood was sufficient to cause the aphonia? He observed that the lateral fragment of the cricoid cartilage had passed forward in such a manner as to be sufficient to cause complete paralysis of the crico-thyroid muscle, and aphonia without effusion of blood. Mr. Stokes did not think they could say that the aphonia was caused solely by the loss of function of the crico-thyroid muscle, or by effusion of blood. It was caused by both. The effusion of blood was very great. The patient only lived a quarter of an hour after the injury, and aphonia came on ten minutes after it. He should therefore regard the effusion of blood as the more immediate cause of the loss of voice, for the laceration of the muscle was caused on the instant of the kick

---

PATHOLOGICAL SOCIETY OF DUBLIN.

January 9th.

A young man, aged 23, a draper's assistant, was admitted into the Mater Misericordiæ Hospital, under the care of Dr. Hayden, in an advanced stage of phthisis. There was tubercular deposition in the right lung, and evidence of excavation in the apex of the left. He had been ill for a period of 12 months, and had spat blood on but two occasions. The larynx was engorged, and he was aphonious. He was put under the ordinary treatment, but suffered from extreme irritability of the stomach, so much so that it was difficult not only to administer medicine but even food. On the 6th January he saw the patient in his ordinary condition; he was then in bed, and rather cheerful, but at 12 o'clock on the night of that day, he was suddenly attacked with hæmoptysis, and discharged about a pint of dark-coloured blood; he complained that he was suffocating, and in less than five minutes he was dead. Dr. Hayden was prepared, on making a *post-mortem* examination, to find the bronchial tubes filled with blood, and he fully expected to find that condition of blood described by Sir Thomas Watson as "an accident of pulmonary hæmorrhage." It would be seen that the left true vocal chord was extensively eroded on the edge; the right vocal chord was slightly tuberculated, the mucous lining of the trachea and bronchial tubes was red in colour. The left lung was found to be extensively solidified, and in the apex were found two large cavities, these communicated with the bronchial tube by an abrupt termination of the latter; both contained dark clotted blood, but the posterior of the two was distended with it; and on carefully examining the cavity, he found a large vessel eroded, and hanging by one extremity into the cavity. He could pass a probe through it with facility, a little plug was found in the open vessel, the bronchial tubes were full of blood. The unaffected portion of the right lung was emphysematous, and the left lung was also emphysematous, where not tuberculous. The heart was in its ordinary condition, the features of interest which the case presented were, the sudden occurrence of death by suffocation consequent on the injection of the bronchial tubes of both lungs with blood, carried into them by a forced inspiration during hæmoptysis. Crossing both cavities in the apex of the left lung were slender isthmuses of pulmonary substance, ensheathing each a blood-vessel; one of these had given way, and been the source of the fatal hæmorrhage; the vessel was a branch of the pulmonary artery, judged by the dark colour of the escaped blood, and by the position of the vessel in relation to the adjacent bronchial tube.

Royal College of Surgeons of England.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College, at a meeting of the court of examiners on the 19th inst., viz.:—Messrs. John Wells Hubbard, St. Lawrence, Isle of Thanet; and John Thomas Redmayne, Clitheroe, Lancashire, students of Guy's Hospital. Edwin Perkins, L.R.C.P. Edinburgh, Manchester; and William Henry Middleton, Darlington, of the Manchester School. John Henry Humphreys, Birmingham; and Alfred John Henry Crespi, Cheltenham, of the Birmingham and University College. Henry Carter Wigg, M.B. Edinburgh, Victoria, Australia, of the University College. James Frederick Parry M'Connell, Allahabad, East Indies, of St. George's Hospital. William Ashley Cox, Bath, of the Edinburgh and St. George's Hospitals. Frederick Stephen Palmer, Brixton, of the Westminster Hospital. Edward Pierce Hardey, Hull, of St. Mary's Hospital. Richard Petch, Compton Terrace, Islington, of King's College. Alfred John Horsey, M.D. Canada, Kingston, Canada, of the London Hospital. John James M'Mahon, L.S.A., Dundalk, of the Dublin School; and John Alexander Howell, L.S.A., Bombay.

The following were admitted on the 20th inst., viz.:—Messrs. William Field Flowers, Tealby, Lincolnshire; Burford Norman, L.S.A., Taunton, Somerset; and Augustus Henry Collet, Worthing, students of Guy's Hospital. James Timotheus Gobart, Jerusalem; William Dobson, L.S.A., Leeds; and James Asbridge Hall, Halifax, of the Leeds School. Richard Corston Wade, Manchester; and Thomas Carleton Railton, Manchester, of the Manchester School. Charles Edward Hoar, Maidstone; and Thomas Lambert Lack, L.S.A., Chichester, of King's College. Charles Jones, L.S.A., Carnaby street; and George Everitt Norton, L.S.A., Upper Baker street, of the Middlesex Hospital. Francis Abraham Holmes, Nassau, Bahamas, of the Middlesex and St. Mary's Hospitals. Charles King Rudge, Bristol, of the Bristol School. Selim Myer Salaman, M.B., Dublin, Maida hill, of the Dublin School. William Moore King, Brighton, of St. Bartholomew's Hospital. George Askew Hull, St. Mary Abbot's terrace, W., of University College; and Robert Laing, Newcastle-on-Tyne, of the Newcastle School.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 27, 1869.

EDUCATIONAL REFORM.—No. VIII.

THE SCHEME OF DR. PARKES.

WE have now nearly cleared the ground for consideration of the curriculum which should be undergone by all who are destined for the medical profession. This branch of educational reform includes the mode in which the various subjects of study should be grouped, the extent to which each subject should be compulsorily learnt; and the examinations which should be passed before the general licence is obtained. It does not include the modes in which the different subjects should be taught, or the nature of the discipline, physical, moral, and mental, to which students should be subjected. We have very distinctly indicated in our previous observations adherence to the principle that the central authority is no further concerned with the mode of study or with school discipline than to afford a general support to all educational bodies in the arrangements which they make for the preservation of order, and to prevent the injury which would accrue, both to the public and to the profession, from the admission of unworthy men through the portals which it is the duty of the central authority to guard. Hence we have almost unreservedly relegated the vexed questions of compulsory attendance on lecture, the comparative values and proper proportions of lectures, and class examinations, and sessional examinations, as well as of professorial and tutorial instruction, to the decision of the individual schools; and if we discuss them further in this series of articles we shall discuss them as school questions, and not as questions for the resolution of examining boards or a central legislative council. Similarly, in discussing the curriculum, we must be understood to be at present discussing it so far as it should be arranged by central authority. We are not laying down now a complete "Scheme of Medical Tuition" after the manner of Dr. Parkes. We are proposing such a scheme of education and examination as in our opinion should be issued by a Medical Council possessing absolute authority in both these respects. Having done that the consideration of the best scheme for a school to adopt would follow naturally, but our immediate object will be accomplished when we have unfolded our curriculum and pointed out the means by which our plans can be carried into effect. And here, at the very threshold, we find ourselves diametrically opposed to the distinguished physician and teacher to whom we have referred, and almost at a loss to comprehend the grounds on which he has taken up the position assumed in his "Scheme of Medical Tuition." His position is, that he accepts the avowedly imperfect arrangement of having a number of different licensing bodies, and then, partly to counteract this pernicious system, and partly on its own merits or demerits, advocates an accumulation of minute regulations to be issued by the Medical Council, and to be binding on all medical schools. He bolsters up one bad arrangement with another arrangement, if possible worse. This will appear from the quotation of two passages from his "Scheme of Medical Tuition." He is arguing against the efficiency of the view so ably urged by Mr. Simon, in his Address to the Medical Teachers' Association after his election as its President—the view that medical education should be left unshackled, and that trust should be placed solely in "the searching nature of the examinations for licences." And what does he say?—

"With our present system of licensing by numerous competing bodies in all parts of the kingdom, it is impossible to ensure such a thorough examination as is contemplated by Mr. Simon. If, indeed, there was one central body for the whole kingdom, organised in proper disregard of those distinctions of race and boundary which all men should desire to efface, we might, perhaps, look for a thorough and searching test. But I fear such a millennium is not for our generation. Even if we had one grand national licensing body, and therefore complete uniformity of examination and knowledge, would it be less necessary than it is now to define the successive steps by which medicine and surgery, and all the underlying subjects, can best be learnt? There must be a right way and a wrong way in setting to work, and an advantage in studying one subject before another. Who is to indicate to the student where he is to begin, and how he is to proceed, and to what length he is to go? Some one must show him; and if the Medical Council or the licensing bodies refuse to do so, their place will be taken by others. But what would be the advantage of allowing this power of direction to lapse from those who are certainly fittest to use it, and of throwing it into the hands of individuals or of schools? It would be merely a transference of action with a decided chance of loss in the transfer."—page 27.

At page 14 Dr. Parkes is arguing that the subjects of study are so extensive in themselves that a selection should be made, and he says:—

"There surely should be a recognised limit—that is, a selection; and if we select we must have uniformity. It may be said that uniformity is impracticable, or, if practicable, undesirable. I entirely distrust this opinion, and, believing that a selection is necessary, submit that it must be official. It can only be made officially in two ways: either by an agreement on the part of all the licensing bodies that their examinations shall be conducted in particular ways and shall fall within certain limits, or by regulations framed by the Medical Council and binding on all schools. I can by no means agree with the views of those who would entirely annul all regulations for teaching. I cannot see how medical education could be carried on without them. Instead of less regulation I would have more, only it should be effective."

From these and other passages it is clear that Dr. Parkes contemplated bringing the medical schools either mediately or immediately under the control of the Medical Council, and producing, for the effect of the regulations which he urges would be to produce, almost one dead level of uniformity in teaching. He goes even so far as to advocate "in Chemistry, Botany, Physics, Materia Medica, and perhaps one or two other subjects, official text-books current in all schools. The Medical Council might undertake the preparation of such text-books. The Pharmacopœia" (*Horresco referens!* the reader exclaims) "has been compiled by a number of experts, working under and directed by a Committee of the Council" (divided into three sub-committees, which again united by means of conferences of delegates from each). "Why in the same way" (Heaven save the mark!) "should not some of our leading chemists and botanists, &c., be called upon to prepare good text-books under the advice of the Council?" Echo answers "Why should they thus be called upon?" "As no profit would be desired" (nor any loss either), "and the expenses would not be great" (estimates vary), "these text-books would be supplied to students very cheaply" (at whose expense?), "and they might be revised, as the Pharmacopœia is, every three or four years." We cannot afford to smile at the innocent simplicity of Dr. Parkes's assurances of the economy of this central issue of compulsory text-books. We have a feeling remembrance of the Pharmacopœia, and "far in advance" our heart is "closed," like "the leaves of the shrinking mimosa." Each text-book would require an extensive series of investigations by all the eminent authorities on the subject of it, innumerable conferences of committees, sub-committees, branch sub-committees, and delegates from all the committees, innumerable references to fresh committees and sub-committees, subsequent revision by a third set of committees and sub-committees, which would report upon the work of the first and second sets of committees and sub-committees, and then at the end of eight or nine years a text-book would be issued at a cost to the profession about equal to the price of the Pharmacopœia.

If there were six text-books to produce, the profession might think itself fortunate if it escaped with a smaller "little bill" than £40,000 for the series. Not content, however, with these *very cheap* text-books, Dr. Parkes would put "the schools to some expense in providing increased accommodation in laboratories, chemical and physiological; in the stock of chemicals and apparatus; in larger drug museums; in microscopes, and other appliances of the kind. I think," he adds, "we may fairly call on the medical schools to provide this increase of stock." Besides putting the schools to this increased expenditure, Dr. Parkes's scheme involves additional teachers in the medical schools. By clipping and paring courses of lectures, adding here and subtracting there, he arrives at the conclusion that there would not be any "material increase in the aggregate cost of education." This is exceedingly consolatory to the medical student, but it is a consolation to be derived at the expense of the poor teachers. "For the augmentation in the teaching staff, providing as it would do for practical and tutorial classes, would have to be met by the introduction of young physicians and surgeons—assistant professors, so to speak—who would thus become trained in teaching and ready to take the higher posts. The payment of these courses would lessen the profits of some of the long courses;" and what is Dr. Parkes's crumb of comfort to the professor, whose bread he is taking away, in order to provide half a loaf for a hungry junior? The complacent suggestion that, "as few men lecture for direct gain, perhaps no objection would be raised to this." We should be astonished at such a broad assertion, if we did not remember that Dr. Parkes is Emeritus Professor of Clinical Medicine at University College, and late Physician to University College Hospital. At that hospital, under the impulse of the most benevolent feelings, the medical officers surrender their fees to prop up a small institution which is always in debt, and only gets a fair supply of surgical cases when a house tumbles down, or an unlooked for railway accident occurs in the immediate neighbourhood. Such a practice is pernicious, and founded on mistaken views of charity. A public resignation of fees fairly earned by an influential and eminent body of physicians and surgeons, does greater injury to the profession by fostering the prevalent error that medical men should render their services gratuitously to charitable institutions. This is bad enough, but authoritatively to introduce a like mischievous principle into medical teaching would be the greatest calamity which could overtake our system of education. One of the chief evils of our present arrangements is the prevalent poverty of professorial pay. Hence we set our faces sternly against any plan which would still further reduce fees for teaching. But we would not be misunderstood. We are not objecting to some of the ends which Dr. Parkes is pursuing, but at the means by which he proposes to obtain them. With some of his proposals we cordially agree; and there are many valuable suggestions in his pamphlet with regard to the modes of teaching particular subjects. We go with him very heartily in desiring to see the accommodation and appliances of the medical schools improved, and in the encouragement which ought to be given to the development of the tutorial system of instruction now thrown unduly into the shade by the overgrowth of the professional system. We wish to see school examinations generally adopted, and we look forward to the time when every man who leaves a medical school obtains his diploma, and goes into practice, will be thoroughly equipped for his responsible task; and this result can never be wrought until every medical student undergoes a complete practical training in the wards of a hospital. And we can go further with Dr. Parkes; we would ask for selection of knowledge, uniformity, and the issue of definite regulations by the Medical Council. *Our* regulations, however, would be *few* and effective, our uniformity would be a uniformity of good examinations; our selections of knowledge would be but as sign-posts to indicate the direct route to the desired goal. Compulsory text-books issued at an immense cost to the profession, and almost given away to the student; compulsory provision of educational appliances; compulsory lowering of fees by a compulsory influx of additional tutors; compulsory uniformity of compulsory tuition, are abominations in our eyes, and abominations of an odour still more evil when combined with tacit acquiescence in a vicious system of examinations and licences condemned by every thinking man. What! Shall we agree to disregard the maxims of political economy in order to prolong the miserable and dishonoured existence of a "Dutch-auction system of diploma selling?" Shall we not agree first to cleanse our Augean stables? A Hercules indeed is required for the task, but as the generation of giants has ceased, let union supply the Herculean strength which this Herculean labour demands. For if the profession be really unisonant, if it really desire uniformity of qualification, if it be determined to remove all obstacles to this consummation, and if it will afford a hearty support to the inexpensive organisation which would effect it, the end could be gained at no distant date.

The Medical Council, refreshed and strengthened by the admission of new blood from the ranks of the profession, uninoculated with the corporate virus, and armed with plenary powers of moral and pecuniary persuasion to influence recalcitrant licensing bodies, would "rise to the height of this great argument." Examinations would become true and rigid tests of efficiency, and the results should gladden the heart of Dr. Parkes, as he sat at the Army Board. No longer would candidates with double qualifications present themselves before the Examiners for the Public Services as hopeless specimens of hebetude and danger—"dull all over"—totally unacquainted with Latin, Materia Medica, Medicine, and deficient in everything but the art of making ridiculous mistakes. No longer would candidates appear who had never heard that "scabies" was the Latin for itch, who would at once amputate a limb for a wounded artery, who would adduce the grasshopper as an instance of a ruminant animal, who would divide aliments into nitrogenous and non-nitrogenous for the purpose of sub-dividing them into albuminous, fibrous, caseous, and gaseous, giving "as an example of the nitrogenous, all vegetables: of the non-nitrogenous, all meats, including carnivora" (carnivora being wrongly spelt), or who, after four years' study, "had not seen a case of strangulated hernia or a case of retention of urine." Through the examinations, for whose speedy establishment we look, no incompetent men should filter—and, this being so, we should be able to trust to free trade in education—we could abstain from hampering our medical colleges by rules, but leave to them that inherent elasticity which, under the pressure of competition, would make them adapt themselves to the wants of medical students, and we could dispense with an ingenious plan which, inasmuch as it exhibits a glaring infraction of the golden lessons inculcated by an Adam Smith, to say nothing of a mistaken apprehension of the mode of procedure which it would become the Medical Council to adopt in furtherance of the ends of the Medical Act, we are almost tempted and inclined to pronounce with Dr. Storrar, "one of the wildest and most impracticable plans ever recommended at the table of the Medical Council."

We have now cleared the ground for a consideration of the Medical Curriculum.

CHOLERA IN INDIA.

In 1864 a code of measures for the prevention of cholera among European troops in India was, under the authority of the local Government, published by the Sanitary Commission for Bengal. Those instructions are now before us, and we have every reason to consider them well calculated to ensure the great and important object for which they were compiled, so long as their execution was entrusted to judicious and competent officers. It would appear that in November, 1867, a Board of Revision was held with reference to some of them, and especially in regard to the paragraphs that advert to the removal of troops from barracks, and the purification of the latter. Certain modifications in the original instructions were proposed by that Board, which, by means of the Army Medical Blue Book for 1866 (page 349), we are now able to compare with the original, and must confess that we fail to see in what respect they either elucidate or are improvements on the original.

Let us give some extracts from the original paragraphs, and of the "modifications" by the Board in question, premising that the Sanitary Commission had expressed itself (paragraph 477) as well aware of the necessity of both experience and care on the part of the authorities at military stations charged with the application of the measures recommended, and expressed it as clear that the removal of troops into camp during outbreaks of cholera also requires judgment, for, as well observed, "to send men unnecessarily away from cantonments into camp, at perhaps the hottest and most unhealthy season of the year, is on many grounds seriously objectionable." Accordingly, it was laid down in paragraph 478 of the "Instructions" that the principal medical officer on the spot was to decide the question of the necessity or otherwise for such a move. We can now the better understand how far the *modifications* throw light upon the instructions as first issued.

ORIGINAL.	MODIFICATION.
Para. 479.—"*If it be admitted by the principal medical officer* that there is reason for apprehending an epidemic outbreak, no option will then remain. The men among whom cholera has appeared must immediately be sent into camp." "It must be ordered that if within one week after the *first* case of cholera *two or more* other cases appear, it shall be considered that the disease has assumed an epidemic form."	"It must be ordered that on the appearance of a second case of cholera in a regiment or battery within one week, the regimental surgeon shall report the circumstance to the Deputy Inspector-General of Hospitals; *this officer will at once examine the case*, and upon him will rest the responsibility of recommending to the military authorities the preparation of the preliminary camp, and the provision of carriage to move the sick. On the appearance of a third case of cholera within the week, on the Deputy Inspector-General will rest the responsibility of recommending the removal of the troops at once, or of delaying the movement till the fourth case, when it shall be considered that the disease has assumed an epidemic form, and the men must be removed accordingly."

Were the object of the "modification" to encourage delay, indecision, and red tape, and to give room for conflict of opinion, it seems extremely well calculated for the attainment of these undesirable ends; thus, instead of holding the senior medical officer at a station directly responsible, a surgeon has first to *report* to him, although that surgeon may be himself an unsafe authority on the subject. Then there is only to result a recommendation to prepare a camp, and then further delay, instead of the prompt and energetic measures recommended by the Sanitary Commission.

In the next place, let us refer to the "instructions" and the "modifications" as they concern the movement of women and children.

ORIGINAL.	MODIFICATION.
483.—"The rules that have now been proposed, as well as those which follow, are generally applicable to the women and children, if cholera should appear in the quarters."	"In all cases in which an unoccupied barrack may be available, the women and children shall be moved into that, instead of into tents, the building having previously been purified."

This certainly is a "modification" with a vengeance, but one that, fortunately for the women and children, can very seldom or ever be carried out. There are, we venture to believe, no Indian stations at which in ordinary circumstances there are any unoccupied barracks. Surely it is not intended that on occasions of cholera outbreaks those persons are to be moved into the barracks from which it has been necessary to move the men, for, were it so, not only would the time required to have them whitewashed and purified, as recommended by the Sanitary Commission and its commentators, be so long that death might in the meantime play terrible havoc among them, but all experience has shown us that so long as the cholera wave hangs over a station it bids defiance to whitewash and other means of purification. The only real measure to be taken is to move the regiment, bodily or in parts, according to circumstances, away from its sphere of influence. Such a measure as placing one set of people in a building from which it had just been found necessary to move another set of people, could surely never have been seriously contemplated; but if it was so, must in the most unqualified terms be condemned. The only redeeming point in that recommendation is contained in its concluding paragraph—"Should no barrack be available, they will be moved into tents in the manner prescribed for the men."

To our mind the original recommendations are explicit, definite, and to the point. We wish we could say as much for the "modifications."

SCOTLAND.

EDINBURGH.

ASSOCIATION FOR IMPROVING THE CONDITION OF THE POOR.

There seems to be a misunderstanding between this Association and the Town Council with regard to the payment of the expenses incurred in anticipation of its formation. A memorial had been sent to the Town Council for a subscription towards meeting those expenses which the Council refused to grant. Dr. Alexander Wood presided at a meeting of a General Committee of the Association. He referred to a statement made by Bailie Stott, at the Town Council, that—

> "Since this Society was set agoing they had had individuals coming up week after week for relief who would never take it before; and the officials of both Parochial Boards found, in going their rounds, that there was scarcely a poor person who would not hold out their hands for charity. It was the greatest evil that they could do to men to cause them to stoop to take charity."

In reply he said :—

> "He only regretted that Bailie Stott's statement was not confirmed by the evidence which they had got. He would just, in conclusion, say that he did think that, considering that the Parochial Boards and the Poor-law managers had been struggling for years to suppress pauperism—and they had the highest authority for stating that, instead of diminishing pauperism, their operations had enormously increased it—they might have expected that the Poor-law managers, and those connected with the administration of Parochial Boards, would have welcomed this Association, and bade it God-speed, and would have done what they could to assist its labours. Instead of that, he was bound to say that they had met with opposition from the very people who had found their utter inadequacy to deal with the great evils of pauperism."

He moved, in conclusion, that this Association is not liable for the debt incurred previous to their formation on the 30th March. The resolution was unanimously adopted.

EDINBURGH HOSPITAL FOR SICK CHILDREN.

From the report read at the annual meeting of the contributors of this hospital, held on Thursday last, it appears that from September till the earlier part of December epidemic fever prevailed in Edinburgh, and a great pressure for admission into the fever wards of the hospital was the result. This demand, from the limited accommodation at their disposal, the directors were unable to meet. They were reluctantly obliged to send away from their doors a large number of applicants; while the patients actually admitted could not be treated in so satisfactory a manner as was desirable, in consequence of the crowded state of the wards, and the impossibility of sufficiently separating the different kinds of fever.

GLASGOW.—UNIVERSITY.

We understand that the Senate, at their meeting on Thursday, conferred the degree of LL.D. on their late colleague, Mr. Robert Buchanan, M.A., for nearly forty years the highly honoured and distinguished Professor of Logic and Rhetoric in the University.

ROYAL LUNATIC ASYLUM.

The annual meeting of the contributors to this asylum was held in the Religious Institution Rooms, on Thursday. The Lord Provost presided. The fifty-fifth annual report, which was submitted by Dr. Mackintosh, contained the following amongst other items:—On the 22nd December last there were no fewer than 603 patients in the asylum, being a much larger number than at any period since it was opened in 1814. Of cures there were 132; those dismissed "relieved" were 83; and one, an idiot child, was discharged "not improved." The deaths have been fewer by nine than in 1867.

CONVALESCENT HOME.

The fourth annual meeting was held in the Religious Institution Rooms. The patients hitherto had been received from the Royal Infirmary, and it was not yet decided upon opening the institution to the general public. According to a statement by Dr. Goff, there had been a considerable increase of patients healed in the Home during the past year compared with the preceding year.

ABERDEEN.

FUNERAL OF THE LATE DR. DYCE.

The remains of this respected gentleman, who died in Edinburgh on Monday, the 11th inst., were interred in the town's churchyard on the following Saturday. Being Professor of Midwifery in the University, and also holding several other public appointments, the funeral procession assembled in the quadrangle of Marischal College. It consisted of the Professors of the University in their gowns, the medical students, and the students of the arts classes in their scarlet robes, headed by the sacrist carrying the mace. The boys of Robert Gordon's Hospital, of which the deceased was physician, were also at the funeral, along with numerous friends of the late Professor, who was very highly esteemed.

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

HOMŒOPATHY.—THE ACADEMY PRIZES.

Paris, January 1, 1869.

Now that the new year has opened—an event that in Paris is a thousand times more thought about than in London—I may, so to say, recommence my work of giving he English profession occasional stray notes of French medical practice and affairs. The delay and loss of some former communications by the French postal department will make me for the future more careful, and I sincerely hope I may not again have to complain of the execrable system, although this week I did not get my **Medical Press and Circular** until it was four days old, and the Saturday's medical journals often do not reach me until yours of the following Wednesday has given me more recent news.

I observe that the late event at Aberdeen is again bringing the question of homœopathy forward, and therefore some notes on the subject may interest your readers. In France I fancy there is not the same unanimity as to professional intercourse with homœopaths that obtains in Great Britain. The leading men, indeed, discountenance it all they can, and are not to be accused of coquetting. At the same time there is not that difficulty of getting a respectable man to meet a homœopath in consultation that is observed in London. On what ground they consent to do so I cannot tell. How they reconcile themselves to take part in consultation with men who are committed to a foregone conclusion passes my comprehension. Yet I see the fact before me. Some say they discuss diagnosis, but not treatment; but how can that be? The homœopaths, if honest and pure, must despise diagnostic acumen. Symptomatology is to them the end. What are changes of tissue to a man who bases therapeutics entirely on the alleged specificity of certain drugs for certain symptoms? I am, of course, supposing that the homœopath is not dishonest, but really cherishes a belief in his system, which, however little it may say for his reasoning powers, does not destroy his conscience. Of such enthusiasts there are, no doubt, a large number in this country.

One of your younger medical contemporaries published in Paris has just opened its columns to a new debate on the Hahnemannian hypothesis. The editor, in a prefatory article proposing to reconsider the judgment pronounced by the profession *against* the homœopathic doctrine, confesses to have met with cases he could not otherwise explain, with results of treatment that surprised him, and with homœopathic physicians in whose good faith and intelligence he had profound confidence. Thereupon he relates a case of pneumonia that occurred in the Grand Hôtel du Louvre. The case in question seems to me to prove nothing, and to be such as could be paralleled by dozens of others left to nature. Our editor, however, follows it by another more novel, and far more to the point, which occurred in his own practice, and for which, therefore, he is responsible. It is to the effect that Dr. Néris, of Martinique, when in Paris, called him in to his son, aged thirteen or fourteen, suffering from acute rheumatism, complicated with heart disease. Your learned colleague treated the lad by nitrate of potassa, colchicum, and a blister over the heart. Later he gave digitalis. Then begins the interesting part of the narrative. This drug gave rise to spasmodic action of the muscles impossible to describe. The boy was intensely agitated, and not a muscle remained at rest for an instant; the pupils constantly opened and closed with violence; the face was greatly contorted; the head rolled about, and rubbed against the pillow continually; the limbs and trunk were in perpetual motion. The mind was equally unhinged, so that no answer could be had to any question. Belladonna, cherry-laurel, valerianate of ammonia, &c., were tried without any effect. Dr. Bouilland was called in after three days thus passed, but could suggest nothing of any use. Hope being abandoned, the unhappy father, seeing his own practice and experience thus useless, said he would try homœopathy, and your colleague at once consented. Two medical men of this persuasion were sent for. They did not arrive together, but each, without any conference, having looked at the patient, told those present that hyoscyamus was indicated. I shall not stop to discuss the doctrine here involved, but hasten on the story. The agreement of the two homœopathic professors so struck the despairing father and his friend that they allowed the trial of globules. A low dilution was advised and administered. From the third dose there was a commencement of relief. The next day the patient was notably better, and the day after he was quite calm.

The editor goes on to say that some of his brethren to whom he has related the case replied that probably a *Paternoster* or an *Ave Maria* would have been equally efficacious. It was but the negation of medicine. But he does not seem inclined to accept this natural solution of his difficulties, nor to cry out, "Perish medicine rather than a prejudice!" He therefore goes on to say that although homœopathy cannot replace our art, it might perhaps take rank as a portion of it. He is therefore willing to re-investigate the doctrine, has determined to open his journal to such new discussion, and introduces to the readers the first of a series of articles contributed for this purpose by the president of the Homœopathic Society of France. Your colleague thinks that if there be proved to be any truth in homœopathy it will be a benefit to advance the day of the reconciliation of the divergent schools, and that to make all medicine, so to say, one, would be to enhance the dignity of the profession. The dissatisfaction of the editor with the dogma he is willing to reconsider, and which he thus commends to his readers, is, however, evinced by his statement of his grave objection, to wit—that homœopathy only touches manifestations, and has no action on the morbid constitution, while it is this constitution that ought to be modified in order to obviate ulterior manifestations. I have given this prominence to the editorial confession of motives for action as perhaps the most important part of the matter, for the first article thus introduced contains but little, though as the matter goes on I may make it a subject for another letter. At present I anticipate your readers will find the above enough.

The following is a list of the prizes for 1870 offered by the Academy. The essays are to be in French or Latin, and sent in before March of that year:—1. The Academy Prize (1,000 fr.), "Traumatic Intracranial Effusions." 2. The Portal (1,000 fr.), "The Condition of the Bones, and especially of the Vertebræ, in Cancer of the Viscera." 3. The Civrieux (800 fr.), "Do Diathetic Neuroses exist? If so, indicate the special characteristics which each Diathesis impresses on each Neurosis." 4. The Barbier (3,000 fr.), for the discovery of the means of curing diseases usually reputed incurable, as hydrophobia, cancer, epilepsy, scrofula, typhus, cholera, &c. Rewards will be assigned to those who seem to have nearest approached this object. 5. The Capuron (1,000 fr.), "The Precursory and Concomitant Phenomena of the Lacteal Secretion." 6. The Godard of 1,000 fr. will be awarded to the author of the best work on internal pathology. 7. The Orfila (6,000 fr.), "Digitaline and Digitalis. Separate the former, and describe the chemical characters which will enable it to be detected in medico-legal investigations. What are the symptoms and pathological appearances observed in poisoning by digitalis?" 8. The Itard (2,700 fr.), for the best memoir or work on practical medicine or applied therapeutics. Such work must have been published for at least two years. 9. The Rufz de Lavison (2,000 fr.), the same question as for 1869—acclimation. 10. The D'Ourches (25,000 fr.); this prize (instituted for the prevention of premature interment) we have described in our number for December 5, p. 649. 11. The St. Lager (1,500 fr.), is to be given to the experimenter who is enabled to induce a tumour of the thyroid by administering to animals substances extracted from the waters or soils of localities where goître is endemic.

◆

The will of Mr. Henry Brown, M.D., surgeon to the Queen's royal household, who died at Windsor on Oct. 24, aged sixty-seven, was proved in London under £45,000.—*Illustrated London News.*

Notes on Current Topics.

Physicians Wanted.

PLENTY, doubtless, are to be found in the profession of pure physic who, were they to see an advertisement in the papers with the above heading, would at once inquire, where are physicians wanted? and what prospects of gain are there in store for them?

The first part of the question seems just now easy enough to answer, for there are dispensaries and other institutions calling out for physicians in vain. The doctors come and look, and shake their heads, and walk off, some to doff the pure physician altogether, and to seek speedy cash returns for their talents in an open surgery, where they compound and dispense their drugs; others to wait for a chance of an opening at a general or a special hospital of name and repute, where they may hope to acquire not only experience, but also the more solid emoluments accruing from private practice. No doubt a hard-working physician, willing assiduously, and for many years, to cultivate the out-door visiting which falls to the lot of most dispensary doctors, may hope in time to acquire some amount of lucrative practice through this channel; but his chances are not to be compared to those of the man who, by becoming early in life connected with a good hospital, escapes the drudgery of visiting among the back slums which surround a dispensary, can study his cases well with every advantage in pleasant and airy wards, is sure that all his directions as to diet and medicine will be faithfully carried out, and in the event of the death of an interesting case, can study its morbid anatomy, unhurried and unmolested, in the *post-mortem* room of the hospital.

As things now go, a man only takes up with a dispensary because he can get nothing else, and with the determination at once to throw up his appointment as soon as something better offers.

The present is eminently a commercial age, and one is compelled to hear men say, "they do not see the good of slaving themselves to death for nothing." Every man likes to feel that he is investing his capital of learning and labour in a way that will tend to pay his house-rent and feed and clothe himself and his family.

It is this feeling that causes so few medical men in the present day to enter upon the uncertain and, for a long time usually unremunerative, career of the pure physician. In the provinces, indeed, the pure physician bids fair ere long to become extinct. One sees often, in the board room of the County Infirmary, a portrait of some healthy, active-looking man, who, we learn, was years ago for miles round the great consulting physician of the neighbourhood, and who amassed almost a fabulous income. All this is now passed; the so-called general practitioners, many of them M.D.'s, are both physicians and surgeons of most competent skill, and people are taught to dispense with the services of the guinea-taking doctor of old times.

Thus we see that, in more than one instance lately, it has been found impossible to procure a pure physician for some of the county infirmaries, and a general practitioner has been elected to, and, we doubt not, has very ably filled, the post. It becomes, therefore, necessary that the physician, even if, as matter of choice, he avoids the practice of pharmacy, surgery, and midwifery, still must in many other respects become more like the general practitioner; while this last, more highly educated than of old, and less of a mere trader in the sale of pills and potions, becomes, in proportion as he is more highly educated, of necessity more self-reliant and less dependent on the aid of consultants.

Mortality in the Hotel Dieu.

VICQ D'AZYR and Lavoisier having been requested by the Academy of Sciences of Paris to compare with respect to their relative mortality the Hôtel Dieu and La Charité, have signed a report in which the following passage occurs:—"The Hôtel Dieu, in fifty-two years, out of 1,008,741 patients has lost 244,720, a proportion of one in four and a-half. La Charité, which has only had a mortality of one in seven and a-half, has lost 168,700. From these statistics results the fearful consideration that the Hôtel Dieu has in fifty-two years cost France 99,044 citizens, whose lives would have been preserved if the Hôtel Dieu had enjoyed as favourable a position as that of La Charité. The loss of life in these fifty-two years represents 1,906 deaths a year, about the tenth part of the total and continuous mortality of Paris. The maintenance of this hospital, or rather of the situation which it occupies, produces therefore the same effect as would a plague which unceasingly desolated the capital."

The Darien Canal.

A PETITION has been presented to the House of Commons by Dr. Edward Cullen, formerly surgeon to Capoey Gaol and Police at Essequibo, in which it is set forth that he discovered, in the year 1849, a practicable line for the junction of the Atlantic and Pacific Oceans by a ship canal across the Isthmus of Darien, by which line the junction might be effected at an estimated cost of six millions sterling, by cutting through ground of very moderate elevation for twenty-seven miles, and deepening the river Sucubti for twelve miles, without any other work, the harbours at each end being admirably adapted by nature for the termination of a grand inter-oceanic canal. That, after further explorations, he succeeded in forming the Atlantic and Pacific Junction Company in 1853, which sent out a staff of engineers to Darien. Dr. Cullen complains that he was not consulted in the conduct of the exploration, but, on the contrary, the direction in which it was made was quite different from that indicated by him as the proper course. That owing to the above cause neither a survey nor even a proper exploration was made; and the engineer-in-chief, after a most hasty, imperfect, and cursory inspection of a part of the country in a wrong direction, reported that a tunnel three miles in length would be necessary; in consequence of which the Atlantic and Pacific Junction Company dissolved, after returning the shareholders the amount of their deposits without any deduction. In the same year the above report was proved to be erroneous by the "Survey of Caledonian Harbour and Port Escoces," by Commander Parsons, which was then published by the Admiralty, and in which a valley is laid down precisely in the position assigned to it by Dr. Cullen. That, after a most careful investigation of the hydrographic and engineering features of the Darien Line, its great superiority over all others has lately been acknowledged by the Superintendent of the Naval Observatory in a report to the Secretary of the Navy. Dr. Cullen concludes his petition with the prayer that the question of the pecuniary advantages that the commerce of Great Britain and Ireland and the British colonies may derive from the opening of a passage for ships between the Atlantic and Pacific might be referred for examination to the authorities at the Board of Trade and the Colonial Office for the information of the House.

Fever at Naples.

It will be remembered that a severe epidemic of typhus was prevalent at Naples last summer, where the bad sanatory condition of the city is proverbial.

Of 5,454 patients received into the different hospitals in the kingdom there were 603 deaths, or 11·70 per 100, while on 2,708 cases observed within the city there were 683 deaths, or 25·29 per 100, a proportion more than double that in the country, which denotes sufficiently the insalubrious condition of the town habitations. In other words, a total of 1,283 deaths in 7,859 patients, due solely to neglect of sanatory laws.

Milk Nourishment.

In his thesis on milk nutriment, M. Leclerc explains accurately the advantages of this form of aliment, pointing out the rules for its use, and the diseases which demand the exclusive employment of milk. Twelve cases, collected from the clinique of Professor Hirtz, illustrate the thesis. The dietary is scientifically established, and the quantity calculated for an adult at four litres. The milk is an aliment of easy and rapid digestion, which leaves little residue, and favours diuresis. It is specially in organic affections, in ulceration of the walls of the digestive tube, in hypertrophy of the heart, and dropsy, that this diet has rendered real service. Patients must follow it out strictly, for the least departure from the rule results in relapses.—*Gazette Médicale de Strasbourg.*

Forensic Medicine.

The prize which was placed by the late Dr. Swiney by his will at the disposal of the Society of Arts, with instructions to them to present on every fifth anniversary of his death to the author of the best published work on jurisprudence a silver goblet, value £100, with gold coin in it to the same amount, was adjudged on Wednesday last, being the anniversary of Dr. Swiney's death, to W. A. Guy, M.D., as the author of a published work entitled "Principles of Forensic Medicine." Dr. Swiney had directed the following committee of the College of Physicians to be associated with the Society of Arts in the adjudication:—James Alderson, M.D.; James Risdon Bennett, M.D.; Frederick John Farre, M.D.; Henry Alfred Pitman, M.D.; Sir Thomas Watson, Bart., M.D.

The Physiciancy to the Irish Viceroy.

We feel most reluctantly compelled to reiterate the protest to which we gave expression some months ago in referring to the appointment of Dr. Oscar Clayton as Surgeon-Extraordinary to the Prince of Wales, a selection which we then denounced as a gross exercise of favouritism, and as calculated to depreciate the office as a position of the highest honour in the profession. The office of Physician to His Excellency the Lord-Lieutenant has with the advent of Earl Spencer become vacant, and the names of gentlemen of the highest professional and scientific repute were mentioned as likely to be selected to the office held under former Viceroys by Sir Henry Marsh, Sir Dominic Corrigan, Professor Banks, and Dr. John Hughes. The honour of personal attendance on his Excellency and the Viceregal family, and of being officially selected for such a duty would have been a prize for many surgeons.

Dr. Nedley, of Talbot street, occupies the seat of Marsh, Corrigan, and Banks, and (truth compels us to say) without the most infinitesimal professional claim to such a position. The gulf which separates the attainments or professional rank of the Lord-Lieutenant's Surgeon under the present Government from that of his predecessors is so wide that we may save ourselves the irksome duty of comparing them, and may content ourselves with the declaration that a more unsuitable selection for the Court Physiciancy, socially or professionally, could hardly within reasonable limits have been made. The favoured gentleman is an estimable general practitioner and a harmonious companion, but he has yet to plant his foot upon the ladder on the summit of which the viceregal surgeoncy ought to be but is not.

Putrid Sausages.

Two sausage makers, Mr. Simmons, of Russia lane, and Mr. Clifford, of Beehive walk, both in Bethnal Green, have been detected in cutting up diseased meat for the sausage machine. We record the fact as our contribution to the publicity which these persons merit, and towards the only penalty—loss of profit—which can reach such traders. We have not the least confidence in police prosecutions in such cases, except as providing an official and public record of their guilt, because the pecuniary fine in which they are mulcted is utterly insignificant as compared with the temptation to commit the crime. Messrs. Simmons and Clifford probably turn every day by the sale of putrid or diseased meat a sum which would cover their police expenses for weeks, and until magistrates are able or willing to mark such persons with the convict's sign by sending them to gaol, the interposition of the law is quite useless. The publication in the newspapers of a list of persons convicted of this wicked fraud would do more than all the bench of magistrates and all Scotland yard towards repressing fraud, yet the great newspaper moralists have stood aloof from the exposure of trade frauds which the *South London Press* inaugurated, and have not ventured to incur the penalty which the shopkeepers of Lambeth inflicted upon Mr. Hughes.

Prevention of Syphilis.

The Contagious Diseases Act has been extended to Colchester, and the opening of the Lock Hospital at that place for the purposes set forth in the Act has been officially notified by the Secretary for War.

Retirement of the Director-General of the Naval Medical Department.

We notice elsewhere Dr. Bryson's resignation and the probability of a curtailment of the emolument of his office. The next officer in seniority for promotion is Sir Edward Hilditch, but we are told that he will not accept office at the reduced salary. After him Sir Edward Deas, the Governor of Haslar Hospital and a veteran of the Crimea, is mentioned. In the list of probabilities Dr. Davidson, C.B., comes next, as an Inspector-General at Greenwich and an active officer during the Crimean campaign. Dr. Salmon, a recently appointed Inspector-General, and Dr. Armstrong, the co-explorer with Sir Robert McClure in the Arctic regions, are also named, and the latter with the additional and eloquent merit of being a favourite at Court.

We believe that it is proposed to interpose a paid executive officer between the Director-General and the Admiralty, and thus to subordinate the office to the glorious empire of red tape. Let us hope that the coming man may have some little knowledge of the service which he is to administer, and may be effective in some other direction than as the medical *echo* of the combatant department.

One-Sided Retrenchment.

THE political atmosphere is heavy with rumours of retrenchment and economy, and the reforming besom is active in the Medical Departments of both the Army and Navy. The Governorship of Greenwich Hospital, a *bonne bouche* of the value of £3,000 a year, is to be set aside for ever. Dr. Bryson, the Director-General of the Naval Medical Department, who has served his appointed five years, has retired, and £300 a year is to be lopped from the salary of his next successor; and it is rumoured that the Professors of Hygiene and Pathology at Netley are to be abolished.

Macte virtute, pueri! By all means let us pare off a shaving from the enormous mass of the public expenditure. Let us have a penny less income-tax by all means; but let us have an even and impartial use of the pruning knife. The economy of foolscap paper, and the curtailment of a few medical salaries, ring loudly in the public ear, but not a whisper is heard of a prudent parsimony in other directions. Which of the extravagant salaries of effete Admiralty Lords and fusty Field Marshals is to be reduced? Where is the redoubtable "Doub" whom the empire was conjured to take care of? Is *his* salary and those of the legion of backstair *protegés* who prey upon the pockets of the never-ending taxpayer to be also reduced? If not we utterly repudiate the parade of economy which, under the pretence of justice and purity, spares the foulest *nuclei* of favouritism, and makes a merit of unflinching curtailment of the emoluments of those whose patronymic is not "Doub."

Devonshire Hospital.

IN our last issue we mentioned that several legacies had been received by the Committee of this Hospital during the past year. The report read at their last meeting was satisfactory in almost every particular. We quote from it as follows:—

"During the year a legal conveyance of the buildings and grounds of the hospital has been given to the trustees by his Grace the Duke of Devonshire, on the condition that they shall be used exclusively for the purposes of the charity, and subject to an annual payment of five shillings. It is impossible to express too strongly the gratitude with which the transfer of so valuable a property has been received. The use of the buildings had been granted to the hospital by the munificent liberality of the preceding Duke of Devonshire; but the legal conveyance of the buildings for ever, and of the valuable and extensive grounds which nearly surround the hospital, have been the charitable act of the present Duke of Devonshire.

"The outlay upon the grounds amounts to a considerable sum; but they detach the hospital for ever from other buildings, and afford a valuable place of resort and means of health to the patients. The walks are now thoroughly drained and gravelled, they are supplied with seats, and they are seen to be much used and valued."

Pauperism and Charity.

THE poor-laws, our charitable supplements of them, and all the circumstances that relate to pauperism and to poverty, are receiving more attention than for some long time past. The MEDICAL PRESS AND CIRCULAR has often had occasion to treat upon points in relation to them, and our readers cannot but be interested in all that passes. While giving some account of the public proceedings that most interest the profession in reference to pauperism, we have thought it well also to make room for the statement of proposals and opinions which, although they may not command the support of some of our readers, will be admitted by all to be of such interest and importance as to deserve the most thoughtful consideration of thinking men. At the same time our columns are open to those who differ from our views, and thus the MEDICAL PRESS AND CIRCULAR affords a platform for the presentation of opposite views, and for impartial discussion of this great subject, on which, unfortunately, too many of our contemporaries have committed themselves to the advocacy of one set of doctrines, and will not so much as recognise others.

IT is certainly a most unfortunate fact that we are still unable to prevent the spread of contagious diseases to the extent of the knowledge in our possession as to the laws of contagion. Thus, if we could but prevent over-crowding, we should soon see a rapid diminution of disease of the zymotic class, such as fevers and the exanthemata. Even consumption, whether contagious or not, is so much increased in frequency by density of population, as has been well shown by Parkes and other writers on hygiene, that to prevent overcrowding in large cities would also do away with the frequency of that great pest of the species. But we certainly are, as a body, too remiss in accomplishing all that lies in our power to prevent the communication of fevers and other very contagious diseases. Thus it would be quite possible to render it illegal to transport any fever patient to the Fever Hospital in a common street cab. A simple way of accomplishing this would be to grant a sum of money from the different parish funds to enable that hospital to send a medical man to inspect all cases of fever demanding admission within its walls, and, if they should be found worthy of admission, to have a carriage belonging to the hospital expressly for the purpose of conveying the dangerously contagious cases to the Fever Hospital. Had Mr. Mill's Bill for amalgamation of the whole of London into one town for the purposes of rating been carried, instead of the silly and trifling Bill of the Tory Government, such measures would be carried out without any difficulty. As it is, the London Fever Hospital, being supported by voluntary contributions, is probably not quite able to support such serious dipping into its funds as would be implied in the sending for fever patients to all parts of the immense metropolis. Hence the use of cabs and the possibility of any of us at any moment being affected with typhus, small-pox, or scarlatina, should we unluckily enter a street cab a short time after the exit of a patient for the Islington Fever Hospital.

HER MAJESTY'S screw corvette "Brisk," just returned from Australia, has brought home a remarkable narrative of the sudden and (we think) unexplained death of its sub-lieutenant. A party, which included the deceased officer, had gone ashore for a day's shooting. He was, and had been, in perfect health and activity. After a couple of hours' sport, he lost his hat, and shortly afterwards separated from his party to follow some game. He was never afterwards seen alive, but his body was found the next day. The surgeon of the ship, Dr. W. D. Smyth, deposed :—

> I hastened to the spot and found the body lying on the left side, the arm bent across the chest, the legs drawn up and fixed ; and, from the rigidity of the joints and stiffness of the body, I should say death must have taken place early in the morning, I should say between five and six o'clock. From the appearance of the face, lividity, and purple hue of the skin, the injection of the eyes, and dilation of the pupils, the immediate cause of death must have been congestion of the brain and lungs, consequent on long exposure to wet and cold ; and as no marks of violence or wound was discovered about the body, I believe that death took place from natural causes. Taking into consideration the great fatigue, hunger, and exposure to wet in the afternoon of the previous day, I think that probably Mr. Robertson overtaxed his strength, and at last became so exhausted that he either fell down on the ground, or sat down from fatigue, and immediately afterwards fell asleep, from which, probably, he never woke. The hailstorms and cold of the night would have the effect of causing the circulation of the blood to become rapidly slower, and thus stagnation of the blood in the lungs and brain would ensue. I do not consider a *post-mortem* examination necessary, as I am satisfied, from the appearance of the body and the history of the case, that death took place from exposure and exhaustion.—Dr. M'Clinton, R.N., sworn: I have examined the body of the deceased, and find him to have been a strong, muscular built young man ; none of his bones are broken, nor were there any marks of violence on his body, and his clothes were thoroughly saturated with wet ; and, from the evidence which I have heard, and from my experience of the climate, I believe that his death was caused by exhaustion brought on by cold, wet, and fatigue. This witness also said that death no doubt ensued within two or three hours after sleep or lying down.—Verdict : Died from natural causes, exhaustion, and exposure to the weather.

We confess we do not see our way as clearly as the medical officers who considered a *post-mortem* examination unnecessary to the conclusion that death arose from exhaustion and cold. An active, sober young officer in the full bloom of youth, with a flask of brandy in his pocket, does not so easily die of exhaustion within a couple of miles of a settlement ; and we hardly think the jury were justified in the verdict which they gave.

THE *Official Gazette of Australia* contains the following notice with reference to the adoption of the British Pharmacopœia :—"In pursuance of the provisions of an Act of Parliament of Victoria, 32 Vict., No. 333, intituled 'An Act to adopt the British Pharmacopœia,' notice is hereby given that the British Pharmacopœia, as published in England under the direction of the General Council of Medical Education and Registration of the United Kingdom, is by the said Act for all purposes substituted in the colony of Victoria for the different pharmacopœias hitherto in use in Victoria."

THE *Union Médicale* informs us the last number of the "Annals of Liebig" records a fact of great chemical interest. Linnemann has effected the direct transformation of fatty acids into their corresponding alcohols—of acetic acid, for example, into ordinary alcohol. He has succeeded by acting on the anhydrous acid with sodium amalgam. This important discovery enables him to complete the series of alcohols from the most simple—wood spirit—to melessic alcohol.

FROM the annual report the health of Boston is found to be in a satisfactory state. The deaths during the last year were fifteen below the average of the last seven years, the percentage being twenty deaths to every 1000 inhabitants.

GREAT alarm has been felt by the inhabitants of Chesterfield in consequence of the number of deaths from scarlatina. It is thought there is fear of further increase. Dr. Black remarked that Beetwell street had been like a large fever hospital. The sanitary state of the town is evidently defective.

SIR HENRY ELLIS, who for nearly thirty years held the office of Principal Librarian of the British Museum, died lately. He was in the ninety-second year of his age.

APPLICATION was made at Derby by one of the medical officers of the Union for an increase of salary on the ground of increased medical duties. He had been in receipt of £80 per annum. It was proposed to raise it to £100, when an amendment was carried that £20 should be given him as a gratuity, the last being an exceptional year.

A SAD mistake occurred at the Derby Infirmary lately. A female nurse gave a patient some lotion ordered to be applied to his thigh, instead of his proper medicine. Though every effort was made to save his life, the poor fellow died.

THE French Emperor, says the *Journal Official*, has just purchased at Orleans the Lamotte Sanguin estate to found there an asylum for convalescent workmen.

DR. W. NEIMAN, medical officer on board the steamer "Smidt," committed suicide lately by taking chloroform. During the last two voyages he had given way to drink, and on the 2nd of December last was reprimanded by the captain. This seems to have affected him, and in a fit of *delirium tremens* he committed the rash act.

IT is said that a young countess in Paris, niece of M. Ferdinand de Lesseps, while riding in the Bois, was bitten on the nose by a fly, and that inflammation immediately set in. Dr. Nélaton was sent for, who decided on an operation, after which gangrene supervened, and within twelve hours the young countess was no more. Whether this is a fact or a *canard* we are not prepared to say.

WE understand that Dr. Bryson, C.B., Director-General of the Naval Medical Service, has resigned in consequence of his term of office having expired, and is waiting the appointment of a successor. Among the inspectors-general eligible for the office are mentioned Sir David Deas, K.C.B., Dr. Davidson, C.B., Dr. Armstrong, and Dr. Salmon.

ACCORDING to the report in the *Toronto Globe*, small-pox is very prevalent just now at Montreal. Vaccination has been much neglected, and there is great fear that the disease, in consequence, may spread through the colony. Where vaccination has been properly attended to, scarcely any deaths have occurred.

Important Medical Trial.

Is the L.F.P.S. Glasgow a Medical Qualification ?

A TRIAL of considerable importance to the medical profession was heard at the Walsall Court on Friday last. Some time ago Mr. Daniel Kerr, who is a Licentiate of the Glasgow Faculty of Physicians and Surgeons, brought an action to recover £4 1s. for surgical and medical attendance on a person named Windsor. The plea of the defendant was that the plaintiff was not duly qualified to practise medicine, and consequently not entitled to recover. Mr. Kerr obtained a verdict in December, however, for £3 11s., but leave was given at the same time to move for a reduction, hence the present action. The whole question turned on the authority of the Faculty of Physicians and Surgeons to grant a medical qualification. It was contended that the qualification granted was a purely surgical one, and the following passage from the charter was quoted among others in confirmation of this opinion :—"It shall not be lawful to any manner of person within the said bounds to exercise medicine without the testimonial of a famous University where medicine is taught." The Act passed in 1850 confirmed this ; and although the Faculty could grant a pharmaceutical diploma, it could not qualify any one as an apothecary. The counsel, therefore, contended that the L.F.P. and S. was only qualified as a surgeon, and could not legally enforce payment for attendance in a medical case.

The judgment given was in favour of this view, viz. :—"I am of opinion that by Section 31 of the Medical Act a person registered is entitled to recover payment according to his qualification to practise medicine or surgery, or both. The plaintiff is registered as a Licentiate of the Faculty of Physicians and Surgeons of Glasgow. I find by their charter and the Act by which it is confirmed, that they can only grant degrees in surgery, and they recognize the fact in their election to fellowships which appear to consist of two orders, physicians and surgeons, whence their title of the Faculty of Physicians and Surgeons. Those only are eligible as fellows in medicine who have been educated in other schools of medicine, whereas their own licentiate, as well as surgeons educated elsewhere, are eligible for their fellowships in surgery. The plaintiff's qualification, as registered, is limited to the right to practise as a surgeon, he being registered as a licentiate."

Notice of appeal was given.

Parliamentary Candidature of Sir D. Corrigan.

THE petitions against the return of Sir Arthur Guinness and Mr. Pim are as we write at hearing, and the current opinion appears to be that the decision will be unfavourable to the election of both the sitting members. We learn that in case the Conservative representatives are unseated, it is the intention of Sir D. Corrigan again to contest the representation of the City of Dublin. It is rumoured that he will be joined in the contest by Mr. Thomas Pim, and will be opposed by the Hon. David Plunkett and Mr. G. W. Maunsell.

Objection to a District Infirmary.

IT seems that there are many difficulties in the way of carrying out Mr. Hardy's Act, although there can be no doubt that in many respects the Act is a good one. The Guardians of the Holborn Union, and parishe of St. James's, Clerkenwell, and St. Luke's, Middlesex, having declined to appoint managers for the Finsbury Sick Asylum District, the Guardians of the Holborn Union have addressed a letter to the Poor-law Board, stating their objections to the late order for creating the district under the circumstances of the negotiations which had passed between the Poor-law Board and the Guardians, and that the Act was not in accordance with good faith. The Guardians remind the Poor-law Board that Mr. Hardy stated in the House of Commons that he asked for the powers to enable the Poor-law Board to take such extreme measures only in cases where the Guardians obstinately and perversely refused to make such amendments in the parochial institutions as were deemed actually necessary. The Guardians submit that a small infirmary is always more useful in proportion than a large one, is less liable to hospital fever, and is more easily managed; that it should be in the immediate locality of the patients to be relieved, whereas the proposed infirmary would be of monstrous size, containing at least 800 beds (one third larger than St. Bartholomew's Hospital), and must in all probability be erected at a considerable distance from any part of the district. They add that the proposed scheme would entail an immense expense, perpetual, and always increasing, on the ratepayers, because the hospital or infirmary will have to be built in the country ; it must have its medical and other staff, &c. The Guardians therefore submit that the proposed Sick Asylum District is altogether a mistake; and they suggest that the sick should remain in the workhouse as before.

THE vacancy in the staff of the Queen's Hospital, Birmingham, caused by Dr. B. W. Foster's resignation on his appointment to the General Hospital, has been advertised. The election will take place on the 29th inst., and Dr. T. P. Heslop, who is unopposed, will be elected.

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. IX.

ONE of the first energetic pulls the external and burnished knob of connexion between the street and my night alarm received was justly attributed to the muscular energy of a palpitating domestic from No. 7, Some street. The flurried maid in gulping staccatos attempted to say, in answer to my query as to the cause of her unexpected visit, that "Master were ill-like, and desired my immediate attendance." I descended from my bedroom, and accompanied the domestic to the residence of her master. We entered it, sought his bedroom, and discovered the object of our anxiety coiled up and comfortable-looking, in bed—certainly the very opposite to "ill-like," if appearances did not deceive us very much.

My presence was duly announced, whereupon Mr. Snigby—the name of the gentleman—assumed a semi-prone position, and acknowledged my obeisance by responding gracefully, as the circumstances of his position just then permitted, optically running over my outline as he bowed, "Welcome, be seated, Sir," he said.

I thanked him and obeyed. Mr. Snigby as he addressed me took a second survey of my lineaments, this time with the scrutinizing eye of a Lloyd's surveyor, who might be half inclined to doubt the strength of keel a double-decker, outward bound and heavily insured, possessed; and the circumstance afforded me the opportunity to do likewise, and to ascertain that Mr. Snigby was a gentleman, whose age had passed the turning point or middle period, whose make appeared to be slim, whose complexion appeared to be sallow—and whose features appeared to be fairly formed, save and except the chin, which was short for his face, and too narrow and compressed to be more than casually observed, beneath a real "Dreadnought" moustache; a glorious pair of eyes, dark brown and expressive, lit up as with torches the countenance of Mr. Snigby, and its surroundings.

Mr. Snigby nodded to his servant, and that self-consuming furnace of anxiety retired from the apartment.

"Your name is Dr. a ——?"

"Quid Nunc, Sir," I replied.

"Quid Nunc? well, how funny! Quid pro quo, Nunc aut nunquam," mused Mr. S., as he shifted his eyes from me to an imaginary doctor perched near to his nosetip, that his musings conjured up, I have no doubt.

I gently enquired the object for which my attendance was sought, and hoped there was nothing seriously wrong.

"Sir," said Mr. Snigby, in reply, as his face assumed a genial glow, "*Had you ever the nightmare?*"

"The nightmare! why no, Sir," I replied, in a rather disconcerted tone of voice, for the question took me by surprise, and I yielded under its influence.

"Sir, I regret it very much indeed, because I am of opinion that a medical gentleman should have in himself experienced the phases of the diseases he may be called on to treat—do you understand?"

I expressed a hope that my patient did not really mean his medical adviser should have been a victim *in propriâ personâ* to asthma, gout, morbus coxarius, phthisis, elephantiasis, and the use of wooden legs ere he became professionally competent to meet the requirements of *his* case, or of any other case known to and recognised by standard nosologists.

My patient was not disposed to qualify the opinion he had formed, and assured me it had not been hastily arrived at.

I regretted that his opinion *was* formed, and hoped that he would reconsider it at an early date.

My patient closed his eyes, bowed his head, and continued, "Sir, I have asked a question, a direct negative has been your reply. *Now,* may I ask, *have I the nightmare?* That's the question. Here, feel my pulse, examine my tongue, look at my pupils—come," and he opened wide his eyes and his mouth, and protruded his tongue, and projected his left arm and hand from him as if they were not his own, but the property of another *body*, and, being so, heartily desired for himself a happy riddance of them.

"No; but you have had it, I presume?" was my bold yet guarded answer.

"Right, Sir. What's the cause?"

"Suppers, ner—"

"Sir, stop! The old, old story. I have been told so often about suppers, which I *don't* eat, and about nerves and about liver, and about the whole of my machinery, that the slightest allusion to *that* subject distresses me."

I offered to my patient a thousand apologies if I were the cause of a single mental pang to his apparently now disturbed condition, and begged he would bear in mind that my observations were attempted to be made in reply to a question asked by himself.

"Sir, true; but suppers and nerves do not account for my nightmare."

"You perceive, Sir," I ventured to remark, "the great centre of the circulation is governed by"—

"Gastric juice," interrupted my patient.

"By natural laws," I continued, "which laws are under the control of"—

"The Commissioners in Lunacy and the Bankside Building Company, Limited," again interrupted my patient. "Sir, stop! I have heard *that* over and over again. It is buncum, stuff, nonsense, and professional padding. I sent for you, *not* to hear a speech, but to get your opinion on my case, although I do not hope to derive benefit from it, for Fata—as I call my nightmare—has tossed in the air, and tumbled in the professional dyke of puzzle and of defeat the leading faculty of this vast metropolis, of Paris, and of that troublesome enigma, the European Continent, Eastern modern wisdom. I have sought and I have found, in the hope of curbing my more than magic high stepper in her mad career, but without deriving the slightest benefit from its wisdom; and the gigantic genius of the skilled, the scientific, and the wise of the New World proved complete failures in her regard. To-night I have had my complaint in an aggravated form; in a form, in fact, such as never before distressed me. I retired to bed at my usual hour, which is ten o'clock. It is now, you say, five to three; very well. Ten and two make twelve, and three make fifteen; three and two make five, wanting five minutes—am I right?"

"Yes, Sir, it is about five hours since you retired to bed."

"Exactly. Well, let me see, I conscientiously consider that the Fata took me at about one thirty, or thereabouts."

"Indeed, Sir!"

"Yes, I think so—but allow me to preface my symptoms by asking if you know what a *nightcap* is, and do you recommend it?"

I boasted full and perfect knowledge of the anatomy of that covering for the "head, or top," as a modernly compiled lexicon defines the article, and did recommend it to some patients, but not as a general rule.

Mr. Snigby smiled. "I don't allude to the textile article, it is the medical nightcap, I mean," he said.

I begged to be excused for the error I committed, and expressed my complete familiarity with the invigorating sedative.

"Sir, I like the posset, and have taken it nightly for years past. I am an army man, sold out you know; have seen some service, under two distinguished generals; often had a brush with an enemy, and many hair-breadth escapes from instant death by sword and fire; and I never knew fear until lately. Sir, would you believe it, that I—I who snapped my fingers at bombshells, and that never feared a column or a troop, have often felt, if not cowardly, decidedly funky, stretched here within the prescribed limits of this unanimated four-poster, Sir, often have I observed without twitch of muscle, the gnawing emissaries of death leave the hell-fire cannon's mouth on the battle field, but at times I fight very shy indeed on a field of down under cover of a floculent blanket."

Mr. Snigby ceased, and sank on his pillow, apparently much distressed in mind, and exhausted in body, for his words were uttered with the marked impulse of sincerity, and he displayed a considerable amount of muscular energy in the delivery of them.

I expressed my regret for, and my sympathy with, Mr. Snigby, hoped to improve his condition, and begged that he would concisely describe the symptoms under which he laboured—that in the present instance I mentally attributed to—his *nightcap*.

SURGERY.

OPERATION FOR STRICTURE OF THE URETHRA.

AT a recent meeting of the Medical Society of the County of New York, Dr. Wood described an operation which he had for some years been performing, and of which he had seen no mention in the practice of other surgeons. Cutting down, after Syme's plan—a staff being fixed at the distal end of the stricture and a slender bougie being also, if possible, passed into the bladder—he had found that, as he approached the urethra by slow and cautious dissection through the fibrinous deposit, the stricture would gradually yield, until, without entering the canal or wounding the mucous membrane, he could by degrees press the staff on towards the bladder. This mode of relieving the stricture answered to the operation for strangulated hernia without opening the sac. He had repeatedly performed it successfully; he had also repeatedly failed, and been obliged to cut into the urethra, as would always be the case in traumatic stricture, or in idiopathic, where the mucous membrane was much diseased. But it was always worth trying, for where applicable it offered the great advantage of rendering urinary infiltration an impossibility. And to such infiltration and the pyæmia consequent upon it were to be ascribed most of the fatal results of perinæal section. (*Medical Record.*)

ACUTE ABSCESS OF TIBIA—USE OF TREPAN—CURE.

M. PEAN showed a patient in whom an acute abscess of the head of the tibia had been spontaneously developed. The disease, which was circumscribed, gave such violent pain as to call forth constant shrieks from the patient. Many surgeons diagnosed a syphilitic inflammation of the bone, and had had recourse to iodide of potassium, but without advantage. Considering the intensity of the pain, and of the acute inflammation which had spread into the knee-joint, and also noticing that the soft parts over the head of the tibia were hot and slightly swollen, M. Pean diagnosed that an acute abscess, only of some weeks' standing, had developed in the epiphysis of the tibia, and threatened any day to give rise to an acute suppuration of the joint. He accordingly applied the trepan, and after having pierced the shell of the bone and removed a portion of the spongy texture, he opened the cavity of a limited abscess, containing pus. From that moment the pain vanished as if by magic, the acute synovitis also disappeared, and the patient recovered his health and strength.

This is a remarkable fact, as proving that, contrary to what is usually taught, an acute abscess of the tibia may follow a course sufficiently rapid to give rise to grave accidents, and, if let alone, to a dangerous form of suppuration of the knee-joint. (*Gazette Medicale de Paris* and *Edin. Med. Journ.*)

DESTRUCTION OF GREAT SYMPATHETIC AND PHRENIC BRANCHES IN REMOVAL OF A TUMOUR IN THE NECK.

THE following case has lately been under the care of M. Trélat at St. Louis.

An abstract only is given:—

E. D., servant, æt. 27, of thoroughly good general health, eighteen months ago began to suffer intense pain in her right arm and neck, and a year later noticed a small tumour about the size of a walnut at the side of the neck behind the sterno-mastoid. The tumour rapidly increased in size, and pain became very severe.

A large tumour was found to project between the trapezius and sterno-mastoid. The skin was non-adherent, colour natural, no pain on pressure. The tumour was behind the right carotid, which it projected forwards, and extended across the middle line, notably displacing the larynx and trachea to the left side. The tumour extended from the angle of the jaw and lower edge of the parotid above, to the sterno-clavicular articulation below. A rounded projection could be felt from the inside of the pharynx. Pain and numbness of both arm and fingers, with tingling, annoy the patient much. The right radial pulse is much weaker than the left, and the superficial veins of the forearm are engorged.

The jugular vein and common carotid had to be dissected off, as also the parotid above and the pleura below; but the tumour was found so firmly attached to the vertebral column and transverse processes, that it could only be removed piecemeal; the bones were then thoroughly scraped; this was very laborious, and involved the destruction of the great sympathetic and of the anastomotic branches of the phrenic. Very little blood was lost.

Next day the face is deeply congested, especially on the right side, which displays well-defined patches of a violet and wine-coloured red. The pupils are unequal, the right being strongly contracted; conjunctiva normal. The breathing is hurried and oppressed. These phenomena are evidently the result of the injury to the sympathetic nerve.

Next day, patient complains of violent pain in the side and over the kidneys; skin hot and moist, pulse 120, dulness at base, and diminution of respiratory murmur up to the middle third of right lung.

Fourth day, all the symptoms much worse. Absolute dulness of lower two thirds of lung. Absence of thoracic movement. Great distension of abdomen. For nine hours before death there was constant coffee-ground vomiting, and expectoration of thick black sputa.

On examination of the wound after death the artery was found uninjured, the vein inflamed and containing a clot. The pharynx and œsophagus were healthy. There was pleurisy, and congestion of both lungs. The stomach and intestines were distended with gas, and contained a considerable quantity of the coffee-ground matter that had been vomited in such alarming quantity. There were eccyhmosed patches on the mucous membrane of the stomach.

The tumour consisted of pure cartilage. (*Edin. Med. Journ.*)

CRETINISM.

ACCORDING to a recent official return, cretinism is by no means on the decline in Switzerland. The cases of this sad and mysterious disease at the beginning of this year among a population of 2,032,119 in the nineteen cantons of Switzerland, amounted to 3,431, and it further appears that there were at the same period 6,258 cases of insanity; thus showing that there is one mentally diseased person to every 202 inhabitants in that country.

NOTICES TO CORRESPONDENTS.

TO CORRESPONDENTS.—We would impress upon our numerous correspondents the necessity of making their lectures, Original Communications, or letters intended for insertion, as short as is consistent with the subject on which they treat. We find it necessary to intimate this to our many friends, in consequence of complaints continually reaching us from contributors, who are anxious to obtain an early publication for their papers.

IN deference to the wishes of a large number of our readers, we intend forthwith to devote several columns weekly to *excerpta* from the best British and Foreign journals, in order to keep our subscribers *au courant* with the progress of medicine and surgery in all parts of the world.

DR. JACOB'S "Lecture on the Eye," with illustrations in six colours, is again unavoidably held over.

A SUBSCRIBER, whose valued support dates from the commencement of this Journal, writing from Scarborough, remarks:—"It would be better when correspondents have anything new to communicate, that they should simplify their prescriptions as much as possible, so that we may know the virtues of remedies we prescribe, and not have to be asked if we can inform persons interested what effect we have noticed after prescribing a certain drug! At this time it shows the great ignorance or want of attention yet prevalent in our profession, more especially in *hospital practice*, where they have such excellent opportunities of observing the effects of remedies; and the *excerpta* you give from the best British and Foreign journals—a sort of *synopsis*—will be found most valuable to those practitioners in the provinces, the majority of whom would never perhaps see the article at all."

SUBSCRIBER.—We are not aware that there is any probability of a vacancy in the department to which your enquiry refers. Resignations are usually kept quiet until a favoured candidate be provided. For authentic information you must try the back stairs of Dublin Castle.

PROSTITUTION.—A subscriber, who has watched the progress of this evil, and the articles that are constantly appearing on the subject in this and other journals, is of opinion that pride and poverty being very much on the increase, the neglect of parental culture in early life, and our very artificial mode of living, are the primary causes of prostitution and its attendant maladies. He would like to hear the opinions of those who have had opportunities for studying the subject, the conclusions they have arrived at, and suggestions for the mitigation of the evil.

Infanticide and Abortion, as suggested institutions, by Erving Whittle, M.D., approved, and shall appear in an early number.

Dr. James Black (Cockburnspath).—We heartily thank you for your note. Such expressions as—"I sincerely wish unbounded success to your valuable Journal, which it merits," are exceedingly gratifying, and encourage us to persevere in the path we have commenced to tread, in order to make the Medical Press and Circular the most practical journal alike to the physician, the surgeon, and general practitioner.

T. H. Sandiford, A B., M.D., on a "Case of Rigid Os Uteri Incision," received, and will appear as soon as space permits.

T. L.—Proof shall be sent you as requested.

Anthrax.—Further interesting cases by Dr. Johnston received.

Dr. Davies (Carmarthen).—The name in favour of which cheques or P. O. O. are to be drawn, appears in the Journal every week, immediately preceding editorial matter.

Mr. Lane.—Your letter shall appear in our next.

Dr. Shinkwin.—Thanks. The extra copies would have been sent earlier but for an unusual sale, which caused the supply to run short.

EVANS'S ELATINE,
OR CONCENTRATED AQUEOUS SOLUTION OF TAR.

Beneficial in cases of Chronic Bronchitis, Asthma, Catarrh, Influenza, and Sore Throat. For Loss or Weakness of Voice it has a surprising action, hence its great value to Lecturers and Singers.

Dose.—A tea-spoonful to two-table-spoonfuls three or four times a day, alone, or in water. When mixed with milk or sugar and water it is very pleasant for children, or with the addition of the syrup of pine-buds. One valuable fact is, that it never disturbs the digestive functions, but, on the contrary, assists and promotes appetite. For Affections of the Chest, taken at bed-time in hot whey, it is especially effective.

EVANS'S
ETHERIZED COD-LIVER OIL.

The addition of Rectified Ether to the Cod-liver Oil is of great value. In numerous cases where Sensitiveness of the Stomach exists the *Etherized* Oil is retained, and the digestive functions assisted for the purposes of nutrition. The pure Oil with Rectified Ether is bright and clear.

No. 1. Rectified Ether, 10 min. to each ℥ij of Oil.
No. 2. Rectified Ether, 15 ,, ,, ,, ,,
No. 3. Rectified Ether, 20 ,, ,, ,, ,,
49 DAWSON STREET, DUBLIN.

DIABETES.
BONTHRON S DIABETIC BREAD AND BISCUITS
Have been approved by the Profession and by Diabetic Patients; contain no starchy matter, and are highly palatable and agreeable.
Country Orders punctually attended to.

AN ARTERY COMPRESSOR, SUGGESTED FOR THE TREATMENT OF SOME SURGICAL ANEURISMS.

By George H. Porter, F.R.C.S.I.,

President of the Royal College of Surgeons in Ireland; Senior Surgeon Meath Hospital and County of Dublin Infirmary; Surgeon to Simpson's Hospital; President of the Surgical Society of Ireland; Vice-President of the Pathological Society of Dublin.

INDEPENDENT of the ligature, various attempts have been made to arrest the current of blood through exposed arteries, and to occlude them rapidly, or by degrees. Most ingenious appliances have been devised for the purpose, but they have never met with much favour at the hands of practical surgeons. Yet how painful it is to meet with cases of aneurism in situations where the experience of bold and able men tells that little can be done to save life! Among those who have endeavoured to close arteries without cutting through their coats may be mentioned Crampton, Percy, Deschamps, L'Estrange, Assalini, Dubois. Their instruments, however, if scrutinized I think it will be found that the disturbance to the vessel both in applying and removing them was too great, and the amount of pressure far beyond that required. In some situations the ligature has invariably failed, secondary hæmorrhage following its separation. To meet those difficulties is my object. That the axillary artery could be compressed between a silver probe and loop of wire for *fifty-two hours* without damaging the vessel, I perfectly satisfied myself. I reported the case in November, 1867. In the instance I refer to the artery was not occluded, but considerably narrowed at the point of acupressure. No laceration of either the internal or middle coat took place, nor do I believe such a condition requisite to close a vessel.

Strongly impressed with such an idea, I consider a modification of acupressure may yet be brought to aid the practical surgeon in the cure of aneurisms hitherto unmanageable. The little instrument I venture to suggest to the profession is in reality a form of acupressure, simple in construction, easy of application, and yet powerful in restraining the current of blood, without rudely inflicting injury on the arterial coats. It consists of a piece of silver wire about the strength of an ordinary probe; this is bent into a triangular shape about four inches in length, and the apex surmounted by a small ring; the base is perforated by two little apertures just large enough to permit a fine wire to pass easily through. The wire is first carried round the denuded artery in an aneurism needle with greater facility than a thick ligature, and each extremity of it passed through the holes in the compressor; one end should be fastened by twisting it through the little ring at the top, and the compressor may then be gently pushed down on the vessel, when, by pulling the free end of the wire, the requisite pressure may be made to arrest the flow of blood through the artery. The lithograph, Plate I., gives an accurate representation of the compressor, and the manner in which the wire is passed through, forming the loop which, with the instrument, encloses the vessel in such a manner that slipping is impossible. When the artery is occluded sufficiently to stop the current, the free wire may be fastened also to the top ring. The instrument can be removed with the greatest facility when pressure is no longer required, by cutting the wire at each side, lifting up the compressor, and then gently pulling the wire away from beneath the artery. I have placed this instrument on the femoral artery in the dead subject, and it closed the vessel so tightly that it prevented the injection of water through the artery, and the internal coat was not in the slightest degree injured. I have not had an opportunity of testing it in the living, but I suggest it to the notice of my professional brethren, hoping that they may be induced to give it a trial. We know that aneurisms have become consolidated, and cured in a few hours after shutting off the supply of blood to the sac, and should such a happy result follow the use of this instrument it might at once be removed without having done any injury to the vessel; or if, on the other hand, it had been permitted to remain for fifty or sixty hours without curing the aneurism, it might be taken away, no harm having been done by its presence. It is so light in construction that no inconvenience is likely to be produced whilst in the wound leading to the denuded artery. Its action imitates, as nearly as possible, acupressure, which we know *efficiently* closes the cut extremities of large arteries. The instrument can be procured at Messrs. Fannin and Co.'s, 41 Grafton street, Dublin.

NOTES ON THE TREATMENT OF FAVUS.

By Henry Samuel Purdon, M.D.,
Physician Belfast Dispensary for Diseases of the Skin.

As a former pupil of McCall Andersons, I have generally adopted his method of treatment, which I have seen successfully pursued at the Glasgow Dispensary for Skin Diseases, in many seemingly incurable cases. It consists in removing the crusts by poulticing, then epilation is commenced, and into the part from which the hairs have been extracted, a solution of the bichloride of mercury, two grains to the ounce, is firmly rubbed in, after which a little sweet-oil is applied. The epilation may have to be performed more than once. This treatment was adopted in the majority of my cases. In November last two boys were admitted at the Dispensary for Skin Diseases, suffering from favus. In both, the crusts were removed as well as possible by poultices, afterwards oil of Cade diluted with glycerine was rubbed in for a day or two, as recommended by Bazin, and which occasioned a "loosing" of some crusts not removed by the poultice. I may remark in passing, that Hebra uses alcohol for the same purpose, which causes a shrivelling up of the cups, crusts, &c. In one of these boys a lotion, containing one drachm of the hypo-sulphite of soda to the ounce, was constantly applied to the head; in the other a liniment, consisting of two grains of carbolic acid to the ounce of olive oil, was the application ordered, and which remedy has been successfully used in the treatment of favus by Dr. Prior, of Bedford (*British Medical Journal*, Oct. 26th, 1867.) It may be briefly stated that the boy to whom the acid and oil was applied became rapidly well, and was discharged cured during the present month, an exceedingly short space of time to be relieved of such a chronic and troublesome complaint; whilst in the other case little or no improvement was manifested; of course constitutional treatment was adopted in each instance. The great point in the treatment of favus seems to be excluding the air from the affected part, which can best be done by the application of oil or ointment, some physicians prefer cod-liver oil. As a local application creosote has the property of preventing the spores from germinating, and is used by many, as also ointments of white precipitate of mercury, dilute citrine, or iodide of sulphur. Neligan employed constitutional remedies and local applications, the former "used with the intention of correcting or altering that vitiated condition of the system generally, to the existence of which is due the development of the morbid growth in a congenial soil, and the latter to remove the diseased mass constituted by the peculiar vegetable parasite, and to prevent its production." Internally he administered iodine and arsenic, in strumous children, cod-liver oil, whilst locally—when the disease occurred on the head—the hairs were cut short, poultices applied to remove the crusts, and the head washed with a strong carbonate of potash lotion, afterwards carbonate of potash ointment applied, over which an oil-skin cap was worn. In two or three days iodide of lead ointment being substituted.

In one of my cases I tried a lotion of sulphurous acid, one ounce to eight of water, but it did not succeed, the head having to be epilated and treated with the bichloride of mercury lotion. I have observed tinea circinata and favus existing together, which case will be found in the *Medical Mirror* for May, 1868. In treating the former affection I now use a solution of chromic acid, a drachm to the ounce, one application of which is generally sufficient. Patients affected with vegetable parasitic diseases require a good nutritious diet, such remedies as quinine, cod-liver oil, and syrup of the iodide of iron being prescribed. It may be interesting to conclude these brief notes with quotations from two of our best authorities on vegetable parasitic diseases, viz., Dr. Tilbury Fox and Dr. McCall Anderson. The first gentleman considers that when tinea circinata and favus exist together, that the fungus of the former disease takes on an active state of growth, and sprouting, forms a favus cup. "We must look for an explanation of the differences between the varieties of tinea, not so much in differences of fungus, as of soil and seat on which they grow."—(*Journal of Cutaneous Medicine*, No. 8, page 390.) Dr. McCall Anderson ("Parasitic Diseases of the Skin,") believes such cases as favus and tinea circinata developed on the same person to be extremely rare, so that they may be considered coincidences, and not as instances of two affections owing to one and the same parasite.

ON THE DIAGNOSIS OF SCARLET FEVER.

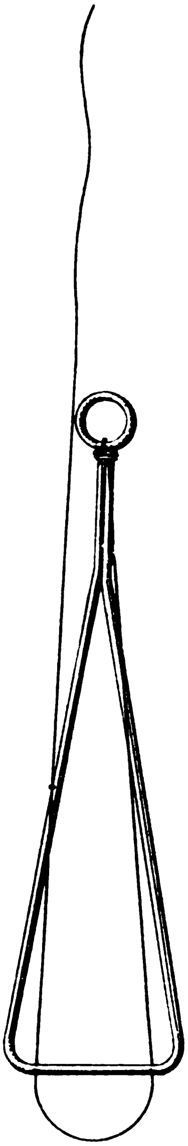
By Dr. Joseph Duggan,
Athenry, co. Galway.

There is, I believe, no disease, in this country at all events, whose appearance in a locality is so much dreaded as scarlet fever, and very justly so; as, for my part, I would almost as soon witness the appearance of Asiatic cholera, as to behold the sad and fatal ravages of this most unmanageable disease, and when it occurs as an epidemic, causes a higher rate of mortality than even cholera itself; of course it is not always the case, but I infer that it does so, as it attacks a larger number of individuals when it spreads as an epidemic—if we calculate the amount of infant, juvenile, and adult mortality, *per se*, of this most dangerous malady, and if we add to this direct mortality the indirect sequelæ of the fever, which very often causes the development of a train of morbid lesions, which induce a fixed and organic disease ultimately ending in early death, or change the previously healthy constitution of the individual into a state of cachexia, premature invalidism, and decay. Now if all these melancholy and fatal results be summed up together, the mortality will far surpass that of Asiatic cholera, indeed it is a most trying and afflicting malady; it is as fatal in the homes of the rich as those of the poor, because it cannot be warded off even by the most exact hygienic measures.

It is liable only to affect an individual but once, like variola and measles, generally during the infantile and adolescent period of life; but no period of life is exempt from its attack, if not previously invaded by the fever. I have seen several old persons die of scarlatina, and on inquiry I found they never had it before; the poison acted so virulently in one of these cases that the patient lived only thirty hours.

This morbid specific poison, which acts on the blood after a definite period of incubation, manifests itself by the appearance of febrile phenomena, inducing the primary fever, which exhibits in a more or less degree great disturbance of the nervous centres, and after the lapse of two or three days the skin is covered with a scarlet efflorescence, and the throat gets tender and painful; of these appearances different grades are to be met with, in some there is only the rash, and no sore-throat, or we have scarlatina and no scarlet eruptions, in others we have merely the febrile sore-throat. In practice we will frequently meet with those phases of the disease, and even between these we will meet with infinite shades and complications not easy to be studied, except by clinical observation. Often it appears in a hybrid form of measles and scarlatina called "Rotheln," and with rheumatism of the joints, when it is called "Dengue."

In the primary stage of the disease, when it is of the



Mr PORTER'S ARTERY COMPRESSOR.

Forster & Co Dublin

utmost importance to form a correct diagnosis, because anxious parents will very justly have you declare (particularly when scarlet fever and measles are rife in the locality) which is which; here any error in the diagnosis, I need not state, would be hazardous to the doctor's fair fame.

Having had some years ago numerous cases of scarlet fever in all its phases under my treatment, I had therefore ample opportunity of becoming acquainted with the disease in all its forms, and from very close observation I have observed at the very earliest invasion of the disease, a peculiar and constant appearance of the eye, so much so, that at the primary stage I could without difficulty diagnose the disease immediately, even in cases where the skin, tongue, or throat have failed to afford me satisfactory evidence that I had to deal with scarlet fever. I have placed such reliance on the peculiar appearance of the eye, that I regard it as perfectly pathognomic of the disease. If once observed accurately it can never be mistaken. I am not aware it has been mentioned by other observers, at least I have not met with it in books. This striking peculiarity of the eye I have never observed in other febrile affections. It is characterised by the eye assuming a peculiar brilliant and glistening stare, like as it were glistened by an ethereal lustre; it has only to be noticed once, then never to be forgotten, and can be easily distinguished from the liquid, tender, watery eye of measles. Where the skin and throat appearances are absent, and therefore Bouchut's pathognomic "white line," I have found this appearance of the eye, combined with the "raspberry tongue," highly diagnostic of scarlet fever, and those who accustom themselves to observe it will have a sure and real sign perfectly pathognomic of the fever.

GLEANINGS IN TOXICOLOGY.

No. III.

ON POISONING BY LOBELIA.

By **Charles Meymott Tidy**, M.B., M.S.,
Joint Lecturer on Chemistry at the London Hospital.

There is no form of quackery more terrible and serious in its results than what is ordinarily termed "Coffinism." As a rule quacks are cautious enough that, whilst they give nothing that by any possibility can do their patients much good, that, at any rate, what they administer shall not do them any harm. Homœopathy is an illustration, and a very good one, of what I mean. Those pretty little round arsenical sugar plums that they call globules may possibly contain arsenic; but, considering that analysis has no difficulty in detecting less than a thousandth part of a grain, but that chemical analysis fails to detect any arsenic in these globules (at any rate, in all the cases I have examined, some five or six), we may very fairly conclude that if there is any arsenic present, it is in such a marvellously minute quantity that we are as certain it can do no harm, as we are perfectly sure it can do no good. So that homœopathy has one great thing to recommend it to inveterate physic takers—that they are dealing with a perfectly harmless and innocent system. And if people are satisfied with it, we have no right to complain. But not so, however, with Coffinism, a name (ominous indeed!) derived from the founder of the system, a "Dr. Coffin," whose patients are to be found in no small numbers amongst our poorer classes, and whose income must be almost entirely derived from their hard-won earnings. But Coffinism deals with no innocent or harmless drugs; nor is it satisfied with any innocent or harmless doses. Starting with their pet, though absurd theory, that "Heat is life; the want of sufficient heat, disease; and cold is death," they administer, with no cautious or measured hand, monstrous doses of cayenne pepper and lobelia to restore *healthy action*, or, what is the same thing to them, *warmth*, to a diseased and broken down system.

Within a very short time I have had two cases of death come before me from, I believe, the absurd practices of these reckless practitioners. I may quote as an illustration the following, where, although I was unable to detect the poison in the stomach, doubtless partly on account of the length of time that had elapsed between death and its administration, as well as from the violent vomiting that occurred shortly after the drug had been taken, still the circumstances of the case leave no doubt in my own mind of the immediate cause of death.

I received from Mr. Rees Llewellyn, July 17th, 1868, by Mr. Humphreys' orders, a stomach and its contents from the body of a child, A. E. B., æt. one year, who died shortly after having taken some mixture obtained from "a Coffinite" residing in Whitechapel. I received at the same time some of the mixture he had prescribed for the child, the greater part of which had been given. The history of the case is briefly this:—The child was taken ill on the 10th of July with a slight diarrhœa. The parents tried some simple domestic remedies, but, the child not getting better, they thought it advisable to seek further advice. Consequently, on the 13th, they consulted the Coffinite. He gave them a bottle of medicine. The parents report that very shortly after the child had taken the "physic," it got rapidly worse, and the symptoms being somewhat alarming, they called in Mr. Llewellyn. They informed him that the sickness had been violent in the extreme, and that the Coffinite had told them to go on with the mixture. Again and again they repeated the dose, but the child never rallied. Mr. Llewellyn immediately suspected lobelia, and took possession of the bottle. He informs me the child was bathed in cold sweats, and was occasionally very convulsed. It died the day after Mr. Llewellyn was first called to see it. The stomach was considerably congested, and contained about half-an-ounce of fluid, which had a slightly acid reaction. I mixed the contents with water, and allowed it to stand for several hours, when I examined the sediment under the microscope, but was unable to detect any lobelia.

There was, however, no difficulty in at once recognizing under the microscope, in large quantities, lobelia seeds and portions of the leaves in the mixture supplied and administered to the child, according to the evidence of the parents. And, judging from this fact, and the symptoms noticed during life, though poison was not discovered in the stomach, for reasons I shall point out directly, there is no doubt whatever that lobelia was the true and primary cause of the fatal result.

The Lobelia Inflata (Indian tobacco) is a native of North America. Its poisonous qualities were first noticed by its effect on cattle that had accidentally eaten it. Many eminent physicians in the United States have from time to time studied its action. It has a somewhat nauseous and irritating smell, and a burning acrid taste, somewhat resembling tobacco. The dried herb, as imported, is of a yellowish green colour, and is usually prepared by the shaking Quakers of New Lebanon (Pareira). It contains a volatile oil which, when distilled with water, imparts to the water the smell and acrid taste of the plant; also an acid which has been termed Lobelic Acid; and, lastly, the active principle of the plant that has received the name of Lobelina, but about which little is positively known.

Although it was not introduced into England prior to 1829, when Dr. Reece proposed it as a specific in asthma, it had become a favourite quack medicine in America as early as 1800. In the year 1809 a man of the name of Samuel Thompson was tried and convicted of poisoning a man with it. Now, lobelia is a poison, not in any way singular in this respect, that is frequently an antidote to itself. And very fortunate indeed is it for many patients that it proves so.

In giving it to animals I have found in many cases such violent vomiting produced that the poison must have been entirely got rid of, for they often recovered after most severe symptoms. In one case, however, in which I gave a small terrier a drachm of the powdered leaves and seeds which were retained, death resulted in about twenty-eight hours and a half. It is most remarkable that the followers of Dr. Coffin still maintain that it is incapable of destroying life. At an inquest, in which I had to give evidence, the Coffinite was most violent in his statements of its non-poisonous qualities, and abusive to those who ventured to disagree with him.

The following case from *Bigelow's American Botany*, vol. i., p. 181, well illustrates the reckless practice of these men in their administration of the drug :—

"A melancholy instance of death, occasioned by the use of lobelia in the hands of a quack, is detailed in the sixth volume of the Massachusetts Reports, in the trial of Samuel Thompson, an empiric practising in Beverley, for the murder of Ezra Lovett. In this trial it appeared that the patient, being confined by a cold, sent for the pretended physician, who gave him three powders of lobelia in the course of half-an-hour, each of which vomited him violently, and left him in a great perspiration during the night. The next day two or more powders were administered, each of which operated by vomiting, and occasioned great distress. In like manner two other powders were given the subsequent day, leaving the patient in a state of great prostration. Several days after this the physician came again, and, finding his patient still worse, administered several more powders, which occasioned great distress, and at length ceased to operate. Finding that the stomach was not sensible to the emetic effects of lobelia, the physician repeated the dose, and when the patient complained of great distress at the breast, and said he was dying, the doctor assured him the medicine would soon get down, or operate as a cathartic. However, on the same evening the patient lost his reason, and became convulsed, so that two men were required to hold him, to relieve which the doctor forced down two more of his powders, and the patient, as was to be expected, grew worse, and continued so until he expired. The doctor, who had thus terminated the disease and the patient at once, was arrested and put upon trial for murder; but the homicide proving a legitimate one, from the want of sufficient evidence of malice prepense, he was acquitted and set at liberty."

So long, then, as vomiting is produced all goes well, but when this becomes impossible, by reason perhaps of prostration of the system by disease or old age, or, the reverse of this, its administration to infants and very young children, then it is that vomiting is not induced, and, failing this, there is nothing left for the wretched patient but death. And this conclusion is forced upon us, that lobelia, in the hands of such men—as careless as they are ignorant—is a most dangerous drug. If it were necessary I could give a long list of cases where death has been brought about by its administration. And I am led to fear, from facts that have lately been brought before me, that similar cases are happening daily, and, indeed, are becoming more frequent.

I may venture to remark in conclusion, that this dangerous trade, this traffic in human lives, demands some immediate legislative interference. Unfortunately, at present, we have been unable to obtain a verdict, in England, even of manslaughter against any of these systematic poisoners, partly because the jury hitherto have taken a merciful, though, I fear, too merciful view, and returned a verdict to the effect that there was a want of malice, and partly because a dead man can tell no tales, and the secret of his death is buried in his grave with him.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. Thornley Stoker, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

MEATH HOSPITAL.

MEMORANDA OF SOME CASES OF FRACTURE.

Under the care of Mr. Collis.

(From the Notes of Mr. Joseph Smith, Resident Pupil.)

I.—COMPOUND FRACTURE OF FEMUR—FRACTURE OF BOTH BONES OF LEG AND OF RADIUS, WITH LACERATION OF ARM.

A labourer, named Michael M., æt. 60 years, having been crushed by a heavily laden cart, was admitted into hospital on the 16th June last, and upon examination was found to have sustained the following injuries :—The left femur was broken obliquely about the upper part of its middle third, and the lower fragment protruded through the integument on the inner side of the front of the thigh, giving rise to considerable hæmorrhage, which, was dependent upon laceration of the Laphena vein. The tibia and fibula were both fractured transversely, about the upper third of the leg ; there was a lacerated wound of the back of the left arm a little above the elbow-joint, and a careful examination revealed a fracture of the neck of the radius of the same side. The hæmorrhage from the wound in the thigh was readily checked by compression, and no carbolic acid being at hand, the laceration was covered with a piece of lint soaked in compound tincture of benzoin, some stimulants were administered, and the whole extremity was covered with a many-tailed bandage; a well-padded tin splint, with a foot-piece attached, was fitted to the inner side of the leg ; a scored splint was placed on the inside of the thigh opposite the fracture, and Desault's splint, padded with a folded sheet, on the outside of the limb ; extension was then carefully made, and a bandage was applied over all. The wound in the arm was dressed, and a dose of Battley's liquor was administered in some warm brandy and water.

Next morning the patient was restless ; had passed a bad night ; complained of the pressure of the splints, which had become displaced, Mr. Collis removed these, and reapplied them in the same manner as before, merely substituting a hair pad for the folded sheet on the outer side of the limb. The man now felt more comfortable, and as no hæmorrhage save a slight oozing had taken place, the dressing was not removed from the wound in the thigh. He was placed on full diet, and having been accustomed to use large quantities of stimulants, was ordered three pints of porter and four ounces of whiskey daily, with an occasional dose of Battley when necessary. The fractured radius was now put up with an anterior and posterior splint, padded well in front, and the limb placed in the flexed position.

For the first few days after the accident the patient was restless and dyspeptic ; his pulse was weak, but never rose very high ; he slept but little at night, and was unable to eat or drink during the day. With a gentle aperient, the administration of easily assimilated food, and a moderate amount of stimulants, he was able in a few days to consume his first allowance, and eat and drink with good appetite. From this time he improved rapidly, and without a single bad symptom. On the eleventh day after the accident the splints were taken off and reapplied, and the dressing was removed from the wound in the thigh, which was completely healed—a result which would doubtless have been attributed to carbolic acid had it been used.

The fracture of the radius was put up on the fifteenth day in a starched bandage.

On the ninety-seventh day the old man left the hospital in a wonderfully good state of health, being able to walk with the help of a stick to his home, and having a very slight halt and some stiffness of the forearm remaining as the result of his injuries.

II.—FRACTURE OF FEMUR OBSCURED BY EXOSTOSIS OF PELVIS.

Stephen McD., æt. 30 years, was admitted into hospital in June last for the relief of injuries sustained by being thrown from a cart. That he had received some injury of the upper part of the right thigh was very evident, but its exact nature was not so apparent; there was shortening and eversion of the limb, with greater mobility than occurs in dislocation; but at the inner side of the groin was felt a large abnormal prominence of bone, and a similar projection behind served to obscure the case, and liken it to a luxation of the head of the femur. An examination into his previous history served, however, to reveal that these protuberances were exostoses of the pelvis, the result of an injury received many years before. The accident was now readily diagnosed to be a fracture of the femur, just below the trochanters. It was put up in the usual way with Desault's splint, which was readjusted as occasion required, and at the end of the third week the extremity was covered with a starch bandage, the patient allowed to move about with crutches, and on the forty-sixth day he was discharged, and returned to his employment with an unimpaired limb.

III.—FRACTURE OF PATELLA.

James McD. was admitted on the 1st of June last; having fractured his right patella transversely whilst endeavouring to recover his balance after making a false step. There was considerable tumefaction of the joint, extending to some distance up the thigh, the upper fragment being two inches removed from the lower one, and the synovial communicated through the fracture with the bursa in front of the patella. Owing to the protrusion of the synovial sac, Malgaigne's hooks could not be used, as they would have opened into the joint. Any attempt to bring the fragments into apposition by the ordinary methods failed, owing to the intense pain which they caused preventing their continuance. The following plan was adopted. Two stout loops of adhesive plaster were fastened above the knee at some distance from each other, and corresponding loops were placed below the joint. A roller was applied to the leg and thigh, omitting the knee; and finally, the proximal loop above was connected by a tape to the distal one below, and *vice versâ*, both tapes passing over pads of lint placed in front of the joint, but not in front of the depression. In this way traction could be borne, its degree easily regulated, and the tapes gradually tightened so as to approximate the fragments tolerably well. Some interval, however, still existed; so about the commencement of the third week Mr. Collis tried the dry suture—stout threads passing obliquely across the front of the joint, through strong adhesive plaster immediately surrounding the fragments above and below—the leg being kept extended and swung in a cradle. The patient was allowed to remain thus for some weeks, the sutures being occasionally tightened. The limb was then put in starch, and the man allowed to move about on crutches. He left hospital on the eighty-fourth day, with only a slight depression marking the site of the injury.

IV.—FRACTURES OF ILIUM AND CLAVICLE.

Mrs. B., æt. 39 years, was admitted, June 14th, suffering from a fracture of the crest of the right ilium, and of the acromial end of the left clavicle, the results of a severe fall. The urine having been drawn off, the fracture of the ilium was treated by means of strips of plaster applied over the seat of injury, running in the direction of the fibres of the external oblique muscle. Whilst the clavicle was put in position by means of the usual axillary pad and bandages, which being found almost useless, were after a few days dispensed with, and that injury treated by position only. The urine required to be drawn off for the first few days, and at the end of that period the strips of plaster covering the fractured ilium were replaced by a carefully fitted mould of gutta-percha. The patient remained in bed for nearly four weeks, when the fractures being consolidated she was allowed up, and left hospital, free from any deformity, on the thirty-first day.

◆

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

MONDAY, JANUARY 18, 1869.

DR. RICHARDSON, F.R.S., President, in the Chair.

Mr. HAYNES WALTON brought forward a double case of conical cornea, on which he had performed four operations. He pointed out the peculiarity of the disease, which consisted in the cone-like growth of the cornea, by which the rays of light which impinged on the cornea were reflected off at such an angle that none which fell laterally entered the pupil, only some of the central, which traversed the apex of the cornea, reached the retina; and as in most instances there is an opacity at the apex, a very imperfect image is formed. Patients so circumstanced are virtually blind. The affection is seen for the most part in young persons. The only relief which can be afforded in this disease is to make the pupil into the form of that of the cat, that is, vertical, and to bring each edge of it to the very margin of the cornea, so that light is transmitted through parts which have not undergone the conical change.

In the present case, the girl, who is twenty-four years of age, was so blind that she could not recognize any of her relations, nor see to get about in the rooms of a strange house. The disease commenced eight years ago. Mr. Walton operated twice on each eye, and the result on each occasion was all that he desired, no inflammatory action having ensued, and no damage was inflicted on the eye.

Now, after the lapse of two months from the last operation, the patient is enabled to read large type, to thread her needle, and to do common needlework. Her distant vision is sufficiently good to enable her to recognize persons in the streets, and to see objects in the shop windows. The girl was then exhibited, and the members of the Society examined her, and tested her powers of vision.

Mr. Walton finally remarked that such an excellent result was seldom obtained, and it is the only instance with which he is acquainted, in which the two eyes of the same individual have been operated on with such an uniform result.

Mr. VICTOR DE MERIC then read the paper of the evening:

HOW SYPHYLIS BEGINS AND ENDS.

The author, in stating the results of his whole experience of cases of Syphilis, discussed its possible initial symptoms under the following heads:—

I. Gonnorhœa.—He had not met with a single patient who suffered syphilitic symptoms after a simple gonorrhœa. The difficulty of diagnosis, however, in females, rendered it impossible to state that the law was infallible, though it appeared to be so.

II. Balanitis.—This he had never known to be an initial symptom of syphilis.

III. Bubo.—This could, the author considered, result from local irritation of the lymphatics propagated to the lymphatic glands, and when thus *directly* produced was not an initial symptom of syphilis.

IV. Simple abrasion.—At first it was probably impossible to diagnose between simple abrasion and commencing chancre. Time, however, solved soon the difficulty.

V. Soft chancre.—The author believed this *could* initiate syphilitic symptoms.

VI. Hard chancre, or hard erosion.—The author entered at length into the subject of this affection as *the* initial symptom of syphilis.

VII. General symptoms.—The author considered that secondary symptoms may be communicated without any obvious primaries.

The question of the endings of the disease was then considered. The disease may prove fatal, usually from phagedæna or necrosis; or it may pass away entirely from the organism, and the patient completely recover. In twenty years' experience the author had met with but twenty deaths.

Mr. Dunn believed that syphilis never commences from secondary symptoms, but can only enter the system by a chancre. The latter may be so small as not to be detected.

Mr. Hunt thought the disease could commence by secondaries; but in these cases the initial symptoms took their origin in the preceding generation.

Mr. Adams related a case in which the evidence indicated secondary manifestations to have been communicated from husband to wife.

Dr. Semple pointed out the danger to science which results from the tendency to declare all anomalous symptoms syphilitic. Reviewing the various points, he considered it probable that primary symptoms must exist before secondaries are manifested.

After some observations by Mr. Wolfe, Dr. Colomiati Meredith, Dr. Camps, Mr. Weeden Cooke, and Dr. Gibbon, the author replied; and the meeting adjourned.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

On the 12th ult. a very important paper was read—

ON THE NATURAL HISTORY OF RHEUMATIC FEVER,

by W. Gull, M.D., and Henry G. Sutton, M.B., of which the following is an abstact:—

The paper brings under the notice of the profession another series of cases of rheumatic fever treated by mint water. It shows the natural course of rheumatic fever with reference to the heart, and in what proportion of cases that organ is involved when rheumatic fever is only treated by mint water. It then considers if there be any evidence to prove that the heart is more frequently involved when rheumatic fever is treated by mint water, or when treated by alkalies, by lemon-juice, or by blisters. This paper is based on twenty-five cases of rheumatic fever, twelve of which occurred in Guy's Hospital, most of them under the care of Dr. Gull, and thirteen occurred in the London Hospital, under the care of Dr. H. G. Sutton. The particulars of the twelve cases have been already recorded in the Guy's Hospital reports, and the remaining thirteen cases are recorded in this paper. Of these twenty-five cases, eighteen were females and seven were males. The average age of the patients was nineteen years. All the patients were suffering from their first attack of rheumatic fever, and the disease was well marked. The temperature of the body during the acute symptoms reached in some cases 104° and 103°; in other patients it was 101° and 102°. Taking an average of all these cases, the temperature was about 102° during the acute stage. The average duration of the acute symptoms, as estimated by the thermometer and general symptoms, was ten days. Taking all the cases that have been recorded by the authors, the average duration was 9·1 days. The total duration of the acute symptoms from their commencement, including the time the patients were ill before coming into the hospital, to their cessation, was on an average seventeen days. The authors next proceed to inquire if the duration of rheumatic fever is longer when treated on the expectant plan, or when treated by drugs; and they consider that no one plan of treatment has any great advantage as regards shortening the duration of the disease. Drs. Gull and Sutton agree with Dr. Barclay in considering that we are not yet in a position to say that alkalies exercise any influence in curtailing the duration of the disease. They are also of the same opinion respecting lemon-juice. With regard to Dr. Herbert Davies's blister treatment, they remark it relieves very much the pain and sufferings of the patients in some cases; but it does not appear to curtail the rheumatic process. And the authors remark, "Our cases appear to us to teach that the rheumatic process runs its course under the expectant treatment as favourably as under the treatment by drugs." Drs. Gull and Sutton next proceed to inquire what evidence there is to show that the drug treatment prevents the heart becoming diseased, and they give a detailed account of the state of the heart in their twenty-five cases. Every one of these twenty-five patients were suffering from their first attack of rheumatic fever, and twelve of the number had organic disease of the heart when admitted into the hospital; two had some, but not very well marked, evidence of organic disease of the heart when admitted; and in eleven there was no heart disease on admission. No organic disease of the heart supervened while under treatment, and the heart was healthy when these eleven patients left the hospital. They remark the experience gained in these cases of rheumatic fever, which were allowed to run their natural course uninfluenced by drugs, tends to prove that, if patients are admitted into the hospital suffering from a first attack of rheumatic fever, and the heart is not diseased on admission, it will very rarely become organically diseased while patients are under treatment. The opinions of Drs. Garrod, Dickinson, Herbert Davies, Geo. Owen Rees, and Basham, are then quoted to show that the heart did not, or very rarely did, become diseased when rheumatic fever was treated in the hospital by full doses of alkali, by blisters, by lemon-juice, or by nitrate of potash, and they observe: "It appears to us that there is not sufficient evidence to prove that any of the advocated systems of treatment have power to prevent the heart becoming diseased. In concluding that the treatment has prevented the heart becoming diseased, we have overlooked the fact that there might be no tendency at the time the patients were under treatment for the heart to become diseased, and our cases show that the good results which have been attributed to the influence of the remedies also occurred when no special remedies were used. Our cases, therefore, tend to teach that these good results were due, not to the drugs, but to the natural course of the disease." The authors then endeavour to show that when the heart becomes diseased in rheumatic fever, it does so at an early stage of the disease; and if it does not become diseased during the first week of the rheumatic fever, it rarely does so afterwards; and they give abstracts from twenty-two cases of rheumatic fever to demonstrate this.

The authors have come to the following conclusions:—

That when the patient's heart was healthy on admission into the hospital, it was very rare for it to become organically diseased while the patients were under treatment by mint water —or, in other words, when the rheumatic fever was allowed to run its natural course.

That the evidence before the profession shows that the heart very rarely became diseased while patients were under treatment in the hospitals, and that this was the case when patients were treated by alkalies, lemon-juice, or by blisters to the joints.

That there is not sufficient evidence before the profession to prove that any of the advocated remedies have power to prevent the heart becoming diseased.

That in rheumatic fever the tendency is for the heart to become diseased during the first few days of the fever; and, should it escape the early days of the disease, there is each day a lessening tendency to its implication. Hence the cases would appear to show that, if at the end of the first week of the rheumatic fever the heart is free from disease, then there is little or no tendency for it to become diseased during the later weeks.

That the reason why the heart did not become diseased when rheumatic fever was treated by alkalies, blisters, and by lemon-juice is to be attributed, not to the influence of the drugs, but to the natural course of the disease; for the patients did not come under treatment until the rheumatic fever had been going on some days, and until the period when the heart was most liable to become diseased had passed over.

The authors conclude by saying: "Hitherto the investigation into the therapeutics of the rheumatic process has been rendered all but valueless by the deficiency in preliminary data. At present, therefore, as regards treatment, our cases seem to show that we are limited to a careful regimen of the patient. Rest, mechanical and physiological—rest in the very outset of the disease. We ought not to wait until the rheumatic process has become well developed in the joints. To regulate the temperature. To moderate excessive skin function by sponging the surface of the body. To allay pain, by placing the patient in an easy position, and sometimes by opiates. To sustain the organic nerve power by light diet, and occasionally by small doses of alcohol. To procure rest by the simplest means, especially avoiding such movements of the body as may excite the circulation. In fine, to place the patient in a physiological state of mean rest, if it may be so termed, of the nervous, the circulatory, the muscular, and digestive systems. To do this fully will often tax all our energies, and require often more consideration than is requisite for prescribing any supposed appropriate drug treatment. We are, therefore, at present, advocates of the exactest treatment of the patient under acute rheumatism, though we may doubt the value of so-called specific drugs."

Discussion adjourned.

CLINICAL SOCIETY OF LONDON.

Sir Thomas Watson, President, in the chair.

ANNUAL MEETING.

The following gentlemen were elected as officers of the Society for the ensuing year:—President: Mr. Paget. Vice-presidents: Dr. Acland, Dr. Burrows, Dr. Gull, Sir William Jenner, Dr. Peacock, Dr. C. J. B. Williams, Sir William Fergusson, Mr. Prescott Gardner Hewett, Mr. Hilton, Prof. Humphry, Mr. Erichsen, Mr. Simon. Treasurer: Dr. E. Headlam Greenhow. Council: Dr. Anstie, Dr. Bristowe, Dr. Marcet, Dr. Murchison, Dr. Pavy, Dr. Quain, Dr. Rendle, Dr. Sibson, Dr. Southey, Dr. Weber, Mr. Alexander Bruce, Mr. Campbell De Morgan, Mr. Durham, Mr. Cooper Forster, Mr. Gascoyen, Mr. E. Hart, Mr Chris. Heath, Mr. Hulke, Mr. Maunder, Mr. Thomas smith. Honorary Secretaries: Dr. Burdon-Sanderson, Mr. Callender.

SIR T. WATSON'S FAREWELL ADDRESS.

This time twelvemonth, gentlemen, I had occasion to thank you for the signal honour you then conferred upon me, in making me your first President. I have now again to offer you my thanks: and I do so in all sincerity, not only for the compliment which you have just paid the other retiring officers and myself, but also, and especially, for the indulgence with which you have been good enough to accept the slender and imperfect service which alone I have been able to render you. I beg leave to add my own congratulations to those of the Council upon the progess and prosperity of our Society during the first year of its existence; upon its increasing number, upon its financial ease, and upon the creditable volume of "Transactions" which it has been able to put forth. I do not feel so certain that I can, with a clear conscience, and in terms as absolute, commend our meetings,—that is to say, ourselves—for the strictest adherence to the professed objects of the Society; which are "the collection of reports of cases of interest, especially of such as bear upon undetermined questions in pathology and therapeutics." I have noticed, and others have noticed—and I take blame to myself for not having from this chair sufficiently discouraged—a tendency to wander beyond our prescribed limits, and to trespass upon the grounds of a kindred and friendly Society, which, if not damaged, might reasonably be offended, by such an invasion. But I am willing to look upon this as merely the unsteady walking of infancy; and to believe that, as we get older and stronger, we shall manage our steps better, and, respecting our neighbours' fences, keep strictly to our own well-marked path. The record of cases, closely observed and accurately detailed, calculated to throw light upon unsettled points in pathology—that is one of the proper and legitimate objects of the Clinical Society; and the investigation of the special action and efficacy of remedies is another, and, in my judgment, at present the more pressing and important of the two. The few words which I addressed to the Society on the evening of our first meeting have been, I fear, somewhat misapprehended. It seems to have been thought, in some quarters, that I had renounced my faith in physic—that I undervalued the resources and usefulness of our art. Such a notion is the very reverse of the truth. I am anxious to have the effects of remedies carefully ascertained and certified, just because I have so great faith in their real force. What I deprecate, what I would fain see altered, what it is one great end of this Society to do away with, is, the vagueness of aim, the uncertainty of result, the merely tentative nature of too many of our prescriptions. Far from thinking that our warfare with disease is a vain warfare, I am only desirous that our arms should have the precision of the modern rifle, instead of the wild flight of the old-fashioned smooth-bore. Probably I have even greater reliance than many physicians upon the virtues of drugs—of what used to be called simples—a word I like, because it helps continually to suggest to one's mind the golden rule, that their administration should be simple; that they should be mixed as little as possible with other substances which might confuse and vitiate the conclusions to be drawn from their actual operation. I am one of those who hold to the doctrine—always within its proper limitations, the limitations assigned by Bacon—the doctrine of final causes so despised by modern philosophy. I believe that those subtle essences which human research and ingenuity have succeeded in deriving from various substances in Nature, and which, when applied to the human body, sometimes even in very minute quantities, have a potency so marvellous as to abolish pain, to compel sleep, to extinguish fevers, to stop for long, perhaps for ever, the recurrence of paroxysms of epilepsy which had continued to recur for years, were implanted in those substances by the Creator, among other uses it may be, for these very services to mankind; and that there lie concealed in other substances, and especially in the vegetable kingdom, many analogous healing powers, which it is a part of man's mission and privilege, and will be his great reward, to search after and to discover. The intelligent and scientific quest of such new remedies; the verification of the exact properties and effects of those we already possess, in order that the active and useful may be rightly applied, and the worthless discarded,—these, I repeat, ending as I began, are or should be, and I make no doubt will be, among the main purposes of this Society. The fruit of its institution, in that direction, will become more and more apparent when the inquiries into particular remedies, which have been entrusted to committees of our members, shall be ripe for report. In bidding you officially farewell, I must express the very great pleasure which your choice of my successor has given me. I heartily congratulate the Society upon its passing under the rule and headship of such a man as Mr. Paget.

◆

SURGICAL SOCIETY OF IRELAND.

(Continued from our last.)

Dr. H. Kennedy read the following paper on

THE DOSES OF MEDICINES.

All are aware that, within a short period, a movement of no little consequence to practical medicine has been commenced; I mean in reference to a more rigorous enquiry into the effects of medicines on the human frame—the science of therapeutics, as it is called. At the inauguration of a new society in London last year, the president, Sir Thomas Watson, took the opportunity of dwelling on the subject at some length, and showing its great importance; and during the present year a periodical, separately devoted to the study of therapeutics, has been published in London, under the joint management of Drs. Anstie and Lawson. Whilst allowing the great value of Watson's observations, and the articles in the *Practitioner*, I would venture to caution my hearers not to expect too much from the movement, and above all not to look for that basis of certainty in medicine which many, in discussing the question, seem to think must result from it. It has been common of late to use such words as "scientific basis of medicine," and other terms of similar import. Now I firmly believe, that this certainty is not attainable in medicine, nor ever will be; and that the idea, if acted on, can only lead to error and disappointment. Does anyone hope the time will ever arrive when, with the disease given, the remedy can likewise be given? Medicine, it appears to me, cannot arrive at such precision; and when we come to reflect on the subject, the reasons are obvious enough, the fact being that the problem is, and must ever be, a most complicated one. I need not speak of the differences of temperament, age, sex, general state of health, symptoms present, the quality of the medicines, the particular preparation used, &c., &c. This is a kind of knowledge which every one must learn for themselves, and very lucky, I would add, they are who succeed in so doing. It reminds me of the attempts made of late years to regulate the treatment of disease by statistics—an attempt which I do believe has done much more harm than good; for it cannot be too strongly impressed on our minds that, if we would avoid routine, every case must be treated on its own merits, and on the symptoms present at the time being.

But some will ask here—Will no benefits arise, then, from the special study of therapeutics? Are the views of Sir Thomas Watson and others only visionary? Far from it. The greatest advantages may, nay, must arise, from their study. But then we must follow in the paths already laid down for us, and must not be looking for that certainty which many speak of as if it were attainable. When our predecessors took up these subjects they dealt with them in a very different spirit, and never even hint at the possibility of a certainty being attained. And it may be observed here in passing, that much more has been done by them in the department of special therapeutics than many suppose. From some observations, indeed, we might be led to think that the idea was quite new, and that nothing had been done by our predecessors in this department of medicine. Now I need not tell my hearers that it is quite otherwise, and that much has been done which would seem to be entirely forgotten. It is to one of these points I venture to ask your attention this evening—I mean the doses in which medicines ought to be administered. From whatever cause it has arisen, certain it is there is a strong tendency to give most medicines, and particularly those of a powerful kind, in smaller doses than was formerly done. But the point has been carried even further than this, for some medicines are now, I may say, entirely eschewed. I need only mention mercury, which is in London looked upon with such abhorrence, and even in Edinburgh it does not seem to be in greater favour. For myself, I believe these to be grave mistakes, and that practical medicine must suffer by such ideas. Short, however, of the total exclusion of some medicines, is the fact that many are now ordered in doses much smaller than they used to be. In such a state of things, would it be any wonder if many became sceptical of the value of medicines? For myself I believe that this very cause has largely contributed to shake the confidence of the profession, or, at least, many of its members, and so to have allowed hydropathy and the other pathies to assume a position they would never have otherwise attained. With these feelings, and in consonance with the move now going on in favour of a more critical study of the effects of medicines, it has appeared to me that advantage would arise by calling attention to the doses in which they are now given in comparison with what was formerly done. It seems to me that if any foundation at all is to be laid, we should at any rate be cognisant of what has been already done; for otherwise we may be going over ground already trodden, and so our labour will be thrown away. I do not know that a more striking proof of this could be given than by referring to one of the numbers of the *Practitioner* recently published, which contains a paper by Dr. Harley, of London, on the Use of Hemlock, chiefly in Cases of Chorea. The paper is a very valuable one, but in the course of it the author observes that the study of the effects of the drug must be commenced *de novo*. This is surely a wrong way to speak of the subject, for of all the drugs of the *Pharmacopœia* hemlock has been probably the one most amply written upon, and its doses, physiological action, and therapeutic effects described with an accuracy which leaves scarcely anything to be desired; and, if my memory serve me right, this has been all done a full century ago. This it will, I think, be allowed, is a striking example in point.*

It has been already stated that my object is to speak of the changes in the doses of medicines which have occurred of late years. To enter into the whole of these would, however, be entirely foreign to my present purpose, were such even possible. It is only the fact that changes have been made to which I would ask a special attention. For the purpose of illustrating this I have selected a few of the most active medicines, where, for obvious reasons, it is of the greatest consequence that the extent to which the dose of each drug may be carried should be known. I need scarcely remind a meeting like this, that in many instances the most valuable effects of drugs are only shown when their physiological action on the system is exhibited. The most familiar example is seen in the use of mercury, where it so often occurs that the disease will not yield till salivation becomes established. This most important principle, though well known and acted on as regards mercury, seems to me not to be so generally recognised in the use of other medicines. But this will be more apparent as I proceed.

The first medicine of which I would speak is arsenic, or, more correctly, " Fowler's Solution," so generally used. Now it is quite certain that the common doses—say five drops three times a day—are in most cases quite sufficient to produce the full effects of the drug, and lead to a cure of the disease. But it does not seem to be so generally recognised that many cases also occur where these doses produce no effect, and that then the dose may be much increased. I myself have repeatedly given ten drops three times a day; and it was only when such doses were given that the specific and curative actions of the drug became evident. This statement is not militated against in the slightest degree by the fact, that there are individuals who will not bear arsenic at all. When, however, this peculiarity occurs, it shows itself from much smaller doses; and no one of course ever thinks of beginning such a medicine in large ones. And speaking of large doses reminds me of having read of even more than ten drops having been given for a dose. With such facts before us, it is scarcely going too far to assert that the effects of this potent drug are even yet but imperfectly known.

A second medicine of which I would speak is strychnine, to which very much the same remarks apply as to arsenic. I have reasons for knowing that this energetic drug frequently fails from not being given in sufficient doses. Not that anything rash is to be attempted, but that, beginning with the common dose of the sixteenth of a grain, it may be gradually increased, and with the greatest advantage; and here, as in other instances, it is only when its physiological action is seen that its valuable effects also appear. I have myself given it in quarter grain doses three times a day, and I know it has been given to the amount of a grain in the day, and with the most excellent results. Probably of all the forms of paralysis the one known as functional is most markedly under the influence of this drug, as well as those forms which are so often met in the hysterical constitution, and which frequently prove so obdurate. It would, however, be entirely foreign to my present purpose to enter further on the subject here.

Of the anodyne class of medicines I have already spoken of hemlock, and of the unaccountable way in which its literature—if I may so speak of it—seems to have escaped the notice of the profession. To this medicine I might add belladonna, which may be, and indeed has been, given in very much larger doses than those ordinarily prescribed. From the active quality of the drug, too, the actual quantity to be given is very small, and in this respect it seems to me to have a very decided advantage over hemlock; and in those cases of chorea where the anodyne treatment is the best—for all cases are not to be so treated—I have found the use of the extract of belladonna, in full doses, of great advantage. This, however, had already been done by others.

In close connection with anodynes, I may allude to digitalis—a medicine which would seem to have gone through many phases. In our present *Pharmacopœia* I find an infusion made of thirty grains of the leaves, which are infused in half-a-pint of boiling water, and of this the dose ranges from two to four drachms. Now I do not say whether this be an efficient preparation or the contrary, but I do say that during the last century the doses given were immeasurably stronger, whilst the results were most satisfactory; and with all this, a degree of caution was used which at the present day could not be surpassed. Hence it is hard to come to any other conclusion than that the infusion of the present *Pharmacopœia* is much too weak, and that anyone using it must be disappointed, and would report of it accordingly. One thing is clear, that we cannot too soon learn what a really efficient dose of this valuable drug ought to be. In connexion with this agent I need not remind the meeting of the very large—I must call them poisonous—doses of the tincture which have been lately recommended, and in many instances given, for the cure of delirium tremens. No experience that I have had, nor, I believe, that of anyone else, would justify such doses. On this question I shall be very glad to hear the opinion of any present.

---

* It is to be observed that it was mainly, but not exclusively, the extract which was formerly used. The preparation used by Dr. Harley was, however, the succus conii of the *British Pharmacopœia*.

The list of medicines I had made out to say something about are, I find, so many, that I must skip a number of them, otherwise the time of the meeting would be too much encroached upon. As it is, however, the principle to which I wish to call attention, my leaving out a number of them is of the less consequence. There are four or five that I would just glance at in the briefest way before concluding. The dilute nitric acid I have used in much larger doses than is usually done, and with very beneficial effects. In several instances as much as half-an-ounce in the day has been taken, and in more than one instance five drachms. Even in smaller doses, as a drachm in the day, it is known it will sometimes induce a state of salivation; but in the larger doses it does this almost with certainty. I have never seen it cause anything like the severe effects of mercury, and the state rapidly subsides when the medicine is stopped. With the state of the mouth there is also a kind of fever set up; and I need not say that, in many instances, this is a very desirable effect to be able to produce. An objection lies against the use of these large doses, inasmuch as the medicine must be fully diluted.

Colchicum is another drug which I have given in very large doses. Like other medicines, there are peculiarities as regards this one, and individuals will be met where even small doses will not be borne. Excepting those, however, many can take it well, and I myself have given it in increasing doses till the patient was taking six drachms of the wine in the course of the day, and I knew the preparation to be a good one. I may mention in passing that in certain forms of dropsy—not those dependent on kidney disease—the preparations of this drug will often be found of the most signal service. Indeed, I do not know any medicine superior to it.

Hippo is another drug on which I would make a passing remark. A few years since, the College of Physicians of this city were made the arbitrators in a serious dispute which arose between two parties in the country. One had given half a drachm at once, and the other accused him of giving a dose which was too large—in fact injurious. Hence the dispute. When the question came before the College some discussion ensued. For myself, I thought the drug was of that class which might be used in what would be called large doses, but I was unable at the moment to give any authority on the point. Since then I have read of the medicine having been given in the dose of a drachm, and this without any remark. I must say I have again forgotten my authority for this, though of the fact I am certain.

The last medicine of which I would here speak is sarsaparilla; and I must say it has often excited my surprise to hear how variously it is estimated by different persons. I have met many who think it is possessed of no virtues whatever, and Mr. Syme, of Edinburgh, says you might as well give so much water. For myself, I have not the slightest shadow of a doubt of its great value; to say nothing of the fact, that many years since it was put to the test of clinical experiment. But this it would now seem has been entirely forgotten. How then are we to explain the marked difference of opinion which exists? Simply, I believe, by the fact that the medicine has not been given in sufficient quantities. I have not a doubt of this as regards Scotland. The decoction of the *British Pharmacopœia* seems to me much too weak, whilst the mode of preparation may, I think, be very fairly questioned. It must be allowed, indeed, that the price which this medicine always commands is a serious objection to its use; but this does not affect the question now under discussion.

In concluding these remarks I have again to repeat that it is the principle of what are the proper doses of medicines I wish to bring under notice. It is true I have alluded to several specially; but this was said more for the sake of illustration than with the slightest idea of doing more than opening up the subject. I had noted a large number of medicines other than those spoken of, and on which it was my intention to have made some remarks. I found, however, that this would far exceed the limits of a paper suited for this place. The more I have thought of this subject the more important I confess it appears to me to be. It constitutes clearly one of the great foundations of therapeutics, and as such seems more particularly worthy of note at the present time, when so much attention is being called to this department of the healing art. I shall be glad to hear the observations of any gentleman present on the subject.

The PRESIDENT said that Dr. Kennedy had brought before them very important questions with respect to some of the most potent agents with which medical men had to deal.

Mr. McDOWELL thought Dr. Kennedy had done good service in bringing this subject under the notice of the Society. The British Medical Association had urged that a committee should be formed for the purpose of making enquiries into the therapeutic action of drugs, and a large fund had been collected for the purpose. He looked anxiously for a report from that committee. As long as there existed such a difference of opinion among medical practitioners as to the effect of drugs, it was a most difficult thing to teach students their action and how to adopt them to the age, sex, and condition of the patients. There were but few principles in the science of therapeutics, and the Society were much indebted to Dr. Kennedy for bringing the subject under their notice.

Dr. HEWITT said the British Medical Association had not occupied itself in anything so useful as the appointment of a committee to consider the subject of the therapeutic action of drugs. It had appointed a committee to investigate the physiological action of drugs, which was altogether a different matter. He had no objection to the investigation of the physiological action of drugs, but when it was said this would throw light on their therapeutical action, he must enter his protest by saying that they need not expect to obtain by the bed-side the same result obtained by experiment on healthy dogs. Not only drugs but food would have different effects in healthy and in diseased conditions of the body. An oyster might be an excellent article of food in one condition of the body—the reverse in another. It was a well known fact that at all times a man could not take the same doses, so to speak, of the same food. A dose of alcohol, which will turn a man's head if taken on an empty stomach, may have no effect when taken after dinner. It was not wonderful, therefore, that medicines would affect the same individual differently in health and in disease. He believed that while an investigation into the physiological action of drugs might yield some valuable results, the experience gained at the bed-side was of more practical importance to the public. Experiments on a thousand dogs would not convince him, for instance, that he had not done good by the use of blue pill. It was said that experiments with digitalis proved that it acted as a cardiac stimulant, but he maintained that it was really a depressant. What did they find at the bed-side? They found that the drug would act upon a pulse which was unequal, irregular, and more rapid than natural, and would bring it down to regular, even, and full action. He contended that this result was due to the depressant action of the drug. While it diminished the number of the heart's beats, the current of blood going on all the time, it must increase the quantity of blood to be expelled at each contraction, and the pulse became fuller because of the greater quantity of blood passing through the artery. In one point of view, therefore, digitalis might be regarded as a cardiac stimulant, but in another it must be considered a cardiac depressant. What they wanted was a thorough investigation of all the conditions which affected the action of drugs. This was a large topic, and involved a principle that had received the authority of the British *Pharmacopœia*. The authors of the British *Pharmacopœia* had tried to determine the doses that medical men should give of various drugs; but Dr. Kennedy had given them a refutation of such an erroneous principle. He had shown that a dose which to one person was perfectly inert, when given to another was absolutely poisonous.

Dr. STEWART observed that at a recent meeting of the British Medical Association it was suggested, that young men ought to try experiments upon themselves as to the action of medicines; indeed, when he was a young practitioner he used to try a great many on himself. He still continued to try experiments with respect to food, and thought he had arrived at some important results. The subject brought before them that evening ought to make them all, young and old, very humble when they saw how difficult it was to ascertain the physiological effect of medicines, so as to be guided in their practical application. He recently heard a lecture from one of the ablest and most practical physicians in Dublin, who, in addressing the students, said, "Gentlemen, the important thing for you to consider is practical medicine," and the only thing he could recommend was an "enlightened empiricism."

Professor **Macnamara** said the important point brought forward by Dr. Kennedy was, that they should be guided in the employment of medicines by the physiological effects of the drugs. There was one medicine which he alluded to, that seemed to be almost forgotten at present—hemlock. He had employed it very extensively of late years; and in looking over the old writers, he was greatly struck with the boldness with which they employed it as compared with the practice of modern physicians. Fifteen or twenty grains of extract of hemlock in the day was no unusual dose formerly; but now there would be hesitation in giving so much. No doubt the extract was prepared now-a-days in an improved manner; still he believed the extract of hemlock in that day was a very good preparation, and that powerful doses of the medicine were habitually given. He believed there was a germ of great therapeutical importance in what had been laid down by Dr. Kennedy, that they must be guided by the physiological effects of the drug. He thought the greatest mistake of the present day was homœopathy. It was a great mistake to send a boy on a man's message; and he firmly believed that giving small doses of opium and belladonna without producing their physiological effects was an erroneous and objectionable practice. They should study the physiological effects which were produced by drugs, and in cases suitable for their administration drive them to those results; then if the medicine disappointed them it must be looked on as having failed; but giving belladonna, for example, in such a dose as to have no effect on the pupil was playing with disease. He had a remarkable case lately in which the homœopathic treatment had been adopted. He gave a proper physiological dose of the medicine, and for the last three days, they thought what was considered to be a hopeless case was getting well. Again, he thought that giving opium in cases of severe pain in doses which did not produce the proper physiological effect of the drug was also trifling with the patient. It would be impossible to persuade him that blue pill had no effect on the liver. This had been attempted to be proved by experiments on animals, the conditions being totally different from those of disease in the human subject. It had been stated that blue pill did not produce a discharge of bile from the liver, which was contrary to the experience of every unprejudiced practitioner. They all knew that a dose of blue pill was followed by a bilious motion. In answer it was said that there was a collection of bile in the gall duct, and that by irritation the duct was caused to empty itself. He asked would aloes produce the same effect? There was no more irritating medicine; it would empty the gall bladder, and they might have a bilious discharge, but afterwards the fæces would return to their former colour. Give the patient, however, five grains of blue pill, and they knew unquestionably, that the bilious motion would last for days, showing beyond doubt that the medicine had stimulated the action of the liver.

Dr. **Athill** asked Dr. Kennedy if he had not found gastric irritation follow from the administration of large doses of nitric acid? He had great faith in that medicine, but he had never given so much as five drachms in twenty-four hours without gastric irritation following. With respect to mercury he thought there was a great mistake in giving up the use of that drug so much as had latterly been done. The day before yesterday he had a marked instance of its beneficial effects. A patient of his was suffering under well-marked jaundice, apparently depending on congestion of the liver. For several days he gave him various purgatives with but little effect. He then gave mercury, and in twelve hours it acted fully, and the next day the yellowness of the eyes and skin was gone.

Dr. **Little** said that it did not follow because medicines were given in small doses that they were always on that account less efficacious or powerful. Dr. Law had shown that the influence of calomel might be increased by giving it in minute doses instead of large ones. With three grains of calomel properly administered they might produce salivation of the patient. He felt convinced that they could lay down no general principle applicable to all medicines. Some would act better in doses which produced no very perceptible effect, while others would have a better result when given in doses that produced more direct and immediate action. As to colchicum, and other drugs of that kind, if their real action is to be produced it must be by minute doses.

Dr. **Kennedy** briefly replied, and said his object was simply to show that with many medicines their therapeutic effects were not shown until their physiological action was produced. With reference to Dr. Athill's question, he had undoubtedly found nitric acid to gripe the patients, but it had not such bad effects as to deter him from using it in tolerably large doses when he considered it calculated to produce a specific effect. As to small doses, that was a subject in itself, and he could give a paper to prove the great advantage of giving some medicines in small doses. His object that evening was to show the extent to which many medicines now in use might be given with great advantage.

The Society then adjourned.

◆

HYDROCEPHALUS, HOUR-GLASS CONTRACTION ADHERENT PLACENTA, FOLLOWED BY PUERPERAL PERITONITIS—RECOVERY.

On December 13 1867, I was called to see Mrs. S., in labour with her fourth child. Membranes ruptured 24 hours previous; waters all gone; position right occipito acetabular; pains were inefficient at my arrival, but in a few hours strong uterine efforts occurred, and the head advanced, but the pains soon ceased again. The os being fully dilated and soft I gave fluid ext. of ergot, and soon promoted uterine contractions, but without any benefit toward the advance of the head. I now made another close examination, and found the diagnostic signs which indicate hydrocephalus. I now made the cause of the delay known to the husband and wife. Now as to my procedure; version or delivery by the forceps were the only alternatives. Unfortunately I left home without my instruments; to send for them was too far, and precious time would have been lost, and delay was dangerous, as the woman's strength was failing, and again, the liquor amnii having drained off so long, made the operation of version very difficult, still I resorted to the latter. I introduced the right hand, "as it corresponded with the face of the child;" sought the feet, and succeeded in the delivery, but had to make considerable traction to deliver the head, which was of enormous size. To all appearance the child had been dead several days. No sooner was the child delivered than there was a sudden gush of blood; without a moment's delay I introduced my hand, found portion of placenta detached; following the cord, I came in contact with a stricture; found that rare complication of labour, hour glass contraction. I overcame the stricture, and by gentle manipulation, the adherent portion of the placenta in the upper chamber was detached, and the contractions expelled, hand and placenta *en masse*. From the loss of blood sustained her strength was gone, and at once had recourse to those measures best calculated to produce reaction.

Dec. 14th.—Thirty hours after delivery, symptoms of puerperal fever developed. Pulse 130. From this date to the 24th the patient passed through a severe attack of puerperal fever, eventually recovering. (*New York Medical and Surgical Reporter.*)

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 3, 1869.

DR. LETHEBY AND THE "LANCET."

IT is a strange thing when men have had dust blown in their eyes that they will not take ordinary trouble to get rid of it. As a rule, when editors have committed egregious blunders, they take some precautions at least not to offend again. Not so, however, with the *Lancet*. It makes blunders after blunders, and with a curious obstinacy, although it has been put right scores of times, blunders on. An outbreak of cholera occurred a short time back. A certain gentleman is sent down to the east end of London, where it was raging, to examine and report on the causes of such a sad calamity. We were not at all surprised, although all the facts were adverse, that he should pitch on the water supply as the cause. A pretty sensational story is forthwith made up. A drain had been allowed to enter the river some distance from the works, and the whole of the evil is at once supposed to originate from this circumstance. It is true this did not occur at the time of the first appearance of the disease ; it is true the polluted water must have passed upward against the current of the stream, and previous to reaching the reservoir have penetrated a huge embankment ; it is true, moreover, that the water thus contaminated, if contamination it can be called (for it is as much like it, we consider, as we heard Dr. Tidy once remark at a meeting of the Medical Officers of Health, as if the waters of Greenwich would be contaminated by a glass of gin thrown in at London Bridge), the water, we say, thus contaminated never was supplied to the part where the outbreak occurred, but to another neighbourhood where it did not occur. But, never mind all this. The public like the idea of water being the cause of all their misery and wretchedness ; and surely there can be no harm in indulging them. And so, when an outbreak of any disease occurs, and after consideration anybody ventures to question whether the water is the culprit aftet all, he must not be astonished at finding himself lashed in the pages of the *Lancet ;* and not unfrequently we recognize the hand who administers the lashing to be that of the same individual who discovered (!) that water, and water only, was the cause of the sad visitation of cholera in the east end of London in 1866.

Dr. Letheby, who is probably better acquainted with the water question than any man living, ventures to differ in opinion with the *Lancet* authorities, and he therefore, this time, comes in for the lashing ; and we venture to think we know the writer of the article of January 9th. But this time the *Lancet* has made a strange blunder. An epidemic of typhoid occurred in North Shields. The water was, of course, supposed to be at fault. Some samples, labelled 1, 2, 3, 4, are forwarded to Dr. Letheby for examination. From his report, which we have seen, we conclude he had no notion whatever why the analyses were required. There is not a word in it from first to last venturing to ascribe a cause for the outbreak. The theories that the *Lancet* have supposed to come from Dr. Letheby were never even suggested by him, and, indeed, we have good reason for believing that he never gave an opinion respecting this North Shields epidemic, and that for a very good reason—because he was never asked. Of course, then, the whole of the remarks in the *Lancet* have originated in a mistake, a mistake, we regret to say, though it is a matter of no surprise that it has not yet been rectified.

The following are the words of Dr. Letheby's report as quoted by the *Lancet*:—"None of the samples contained anything positively injurious, although No. 1 might be at any moment charged with drainage matters in the unoxidized state, and none of them were fit for domestic use."

This report the *Lancet* calls mysterious ! For our own part we must admit we never read a more plain, unvarnished statement. It may be mysterious to the writer of the article, but Dr. Letheby, we are sure, never undertook to provide him with comprehension. We have not a doubt Dr. Letheby came to this conclusion, from the large amount of nitrates reported in this sample ; and we all know that the water would become dangerous if the oxidation process was in any way hindered or impeded. As it is, it does not contain anything positively injurious, as Dr. Letheby remarks, but it is easy to see how necessary his caution is.

We would venture to give the *Lancet* a friendly hint, that in future it might be advisable to employ gentlemen who understand the subject about which they are writing. We are bound to believe that the writer of the leader in question had never seen Dr. Letheby's report, and that he has concluded that the views expressed by Mr. Hawksley are those of Dr. Letheby (which we are sure cannot be the case); or else that he has written in total ignorance of the whole subject, which is, perhaps, the most charitable conclusion after all.

⁂ Since writing the above the *Lancet* has been good enough to favour us with another article on the North Shields epidemic, confessing to a certain extent the error it committed. The opening sentence admits what we supposed was the case, that the writer had never seen Dr. Letheby's report. We really hope this will be a caution for the future, as this sort of bungling in our leading medical journal is a serious matter. The *Lancet* is kind enough "to acquit Dr. Letheby of any share in Mr. Hawksley's opinions." We should think so.

RHEUMATIC FEVER AND ALKALIES.

THE admirable debate in the Medical and Chirurgical Society, which has occupied two evenings of that august society's term, will long be remembered in the annals of therapeutics. It is indeed a sign of the times that such a debate could take place at all. Dogmatism is very common, and intolerance has, we may almost say, been quite as rife in medicine as in theology, and the *doxy* or opinion of a few in commanding hospital positions has too much been considered as the voice of the Deity, not admitting of being questioned. It has been asserted by John Hunter and others that mercury must be used in syphilis. It is equally asserted by Dr. H. Fuller that the use of alkalies in rheumatic fever is a *sine qua non* of good treatment. To be sure, the same assertions were made by M. Bouillaud as to the efficacy of excessive depletions of blood, and the treatment by nitre and by lemon juice has been vaunted as a wonderful prevention against the heart disease which so frequently accompanies rheumatic fever. But, alas for human endeavours, it appears as a consequence of the recent statistical experiments so carefully made by Dr. Gull and Dr. Sutton, that the very same admirable results as those supposed to be obtained by bleeding, by blisters round the joints, by enormous doses of alkalies, &c., &c., may be obtained by letting the patients lie snugly in bed, and giving them no medicine at all. Dr. Fuller, who may now almost alone be looked on as the champion for the alkaline treatment, since Dr. Garrod has not appeared in the field to assert its virtues, observes that whenever he had a case of rheumatic fever to treat in his wards, when no heart disease existed at the moment he undertook the case, this sad complication never had presented itself to him in the course of the disease treated in the hospital. To this Dr. Gull replies, and, we believe, with very great truth. Heart disease, if it is to appear at all, is one of the first symptoms in rheumatic fever. Its period of invasion is within the first week. Hence Dr. Fuller's argument in favour of alkalies on that score begs the question. The same may be said of all careful hygienic treatment. Dr. Handfield Jones observes truly that rheumatic fever is not like measles or scarlet fever, &c., a disease which runs a definite course. Sometimes it lasts only a week, sometimes a month or six weeks, and hence statistics are very fallacious in the deciding as to the treatment which is most efficacious. Dr. Wilks, in a speech full of vigour and truth, points out the enormous importance of learning what is the natural course of such a disease as the one in question. Two years ago, he observes, a non-medical gentleman heard a debate on the treatment of rheumatic fever, and, on hearing that each physician vaunted the value of some different mode of treatment, he remarked that he was convinced that it was probable, from such conflicting evidence, that the disease spoken about would get well of itself without treatment. And, indeed, this appears to be the case. After the very exhaustive debate in the Medical and Chirurgical Society, few can doubt that there is but very little difference in the results of the various treatments proposed for this formidable affection. We would make one remark, *en passant*, that statistics are of but doubtful service in cases of such a disease as rheumatic fever. The cases coming before our notice present such a variety of intensity, that in this, as in many other questions, twice two do not make four. You cannot compare numerically unlike things; and everyone knows that rheumatic fever in young persons under twenty is far more productive of heart disease than the same disease among adults. There is one remark which we would make in conclusion, and that is that the discussion of all disputed questions such as this should be encouraged as much as possible by the Council of the Medical and Chirurgical and other societies. Were this only done, we might ere long come to an end of medical dissent; and if we could but make up our minds to accept without reserve the principles contained in the magnificent essay on "Liberty" by the great master of philosophy, Mr. Mill, we might soon allow all manner of opinions to be heard without difficulty, certain that truth has but one enemy, and that is silence and avoidal of discussion.

OUR ARMY MEDICAL OFFICERS.

Two of the daily journals have of late applied very harsh language to our brethren in the army; telling them, in very plain terms that they are inferior in quality, over numerous in quantity, and that the sooner a large number of them are abolished the better it will be, not only for the purse of John Bull, but for the interests of the soldier and service generally. The Netley professors very properly came to the rescue, declaring that the qualifications of the men who during the last sixteen years have entered that branch of the public service are, as regards professional attainments, fully equal to the best class of those who enter private practice; but, so far as we have seen, no advocate has appeared to plead in bar of the threatened reduction among their ranks.

The facts require to be borne in mind, that no set of officers connected with the army spend so much of their service abroad as do those of the Medical Department; among none is the proportion of invaliding so great, and among none the rate of mortality so high; that with the existing establishments much difficulty is experienced in supplying the requirements of foreign stations, and that with a diminished number of officers, to do so would be utterly impracticble. No doubt, if a reduction in the number of effective troops takes place, a corresponding reduction may be effected in their officers, medical as well as military. Whether such reduction in the army can under existing circumstanees take place with just regard to public interests is a question beyond the sphere of the professional press; but it is within our province to protest as we do against a measure calculated to cripple the efficiency of that army and tell severely against the wellbeing of the individual soldier.

We do not say, however, that no room exists for reductions in the establishments connected with military hospitals; on the contrary, we are well aware that several could be effected, not only to the benefit of the taxpayer, but to the great benefit of the service. We allude more particularly to the military staff attached to hospitals, including governors, captains of orderlies and so on, none of whom can be of any other use than that they complicate administration, which should be left entirely to the medical officers, who, were the power given them, could effectually, and with less cost than is at present incurred, conduct the whole duties connected not only with the treatment, but general management of the sick. We see no reason why the administration and discipline of the Army Hospital Corps should not be left with the Medical Department under whom the larger portion of its members are employed; and in regard to the Purveyors' Department, there is every reason to believe that amidst the ensuing changes its position with reference to hospitals will be considerably modified, to the advantage of the latter.

◆

SCOTLAND.

EDINBURGH.

THE NEW MEDICAL HOSPITAL.

We are informed that the different local committees appointed by a deputation from the acting committee in the various country districts are forwarding the contributions to this institution. In addition to subscriptions already reported, the following sums have been received: From Kelso, £754; Falkirk, £185; Larbert, £101; Lanark, £167; Dunbar, £117; Haddington, £84; Selkirk, £51; and Lauder, £111.

VALUATION OF WATSON'S HOSPITAL.

The greater part of the business at the meeting of the Edinburgh Merchants' Company last week turned on this point. In answer to a question put by Mr. M'Laren, M.P., the master explained the charter on which the grounds were held by Watson's Hospital from Heriot's Hospital, after which Mr. M'Laren gave an interesting sketch of the subject, in which he stated that it was his opinion that Watson's Hospital could sell the grounds to the Royal Infirmary; and that there were encumbrances on the land which prevented it being feued for building streets. From the report of the sub-committee it appears that this is the least expensive site, whether the best is still *sub judice.*

SCOTTISH METEOROLOGICAL SOCIETY.

This society held its half-yearly general meeting in Cragie Hall this day week. The Marquis of Tweeddale, President of the society, in the chair. After the report had been read and adopted, several communications were presented to the meeting, among which was one by Dr. Mitchell on "Temperature and Mortality," which he calls "curves." He said these curves referred to London, and that they might be regarded as exhibiting the normal relations of temperature and mortality. He observed that the year begins with the curve of mortality at its highest, and the curve of temperature at its lowest The two last weeks in December and the three first in January, as usual, show the coldest continuous weather in the year, and to this the high death-rate may almost with certainty be attributed. The causes of death during this period we believe to be largely made up of diseases of the respiratory organs, fevers, and the debility of old age and infancy. In the end of January and the beginning of February there occurs a period of comparative warmth, and we are chiefly concerned to see if its occurrence affects the march of death, which it apparently does, for with this rise of temperature in the end of January and the beginning of February we find a lowering of the death-rate. After this there comes a week of exceptional cold. We call it a period of exceptional cold because the temperature is lower than that both of the days preceding and following it. This deflection of the curve occurs with remarkable constancy from year to year, and its occurrence appears to have an influence on the death-rate, for, as the mortality fell with the rise of temperature during the warm period to which reference has just been made, so it rises here with the fall of temperature. From this point of the curve—that is, the middle of February—the deaths keep rising till the end of March, though the temperature, so far from falling, rises also with more or less steadiness from week to week during the same period. There are reasons for believing that the increased mortality here is due rather to the arid polar winds of spring than to a low temperature, and we know that deaths from inflammatory diseases of the respiratory organs prevail more at this than at any other season of the year. From the beginning of April to the last week of June, the temperature may be described as steadily rising, and the mortality is steadily falling. He then notes the peculiarity throughout the year, from which he considers that when the temperature is above 58° the disposition to death is by the abdominal organs, and the temperature and mortality tend to rise and fall together; but when it is below 56°, the disposition to death is by the organs of respiration, when the temperature and mortality assume an inverse ratio. We have not space to follow him through the whole year, and can only remark that the paper is an interesting one, and worthy of consideration.

A new scheme for supplying the city of Edinburgh with water has been proposed by Mr. Roderick Coyne, C.E., and submitted to the magistrates and council. To meet the expenditure a rate of only 6d. per pound would be required, which he believes might in ten years be reduced to 3d. in the pound. Mr. Coyne estimates the co t of his scheme at £280,000.

DUNDEE.

ROYAL ORPHAN INSTITUTION.

At a meeting of the directors of this Institution, it was resolved to proceed with the erection of the new institution on the site at Craigie Terrace. It was also resolved to purchase other three-quarters of an acre of ground, so that the whole extent of ground might be two acres. Mr. J. S. Guthrie, the proprietor, had also presented £300 to the Institution.

ABERDEEN.

Several gentlemen are candidates for the chair of Midwifery in the Aberdeen University, vacant by the death of Dr. Dyce. The duties are discharged by Dr. Angus Fraser until the election takes place.

The late Mr. Davidson, of Balnagask, among other legacies, has left £1,500 to various charities in Aberdeen, specifying particularly the Royal Infirmary, the Asylum for the Blind, and the Ragged Schools and Reformatories. Also £100 each to the Scottish Corporation, London; the Caledonian Asylum, and the London Hospital, Whitechapel.

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, January 27, 1869.

One of the favourite topics of gossip the last two or three weeks has been whether Dr. Brown-Sequard will occupy the Chair of Comparative Pathology here. It has been quite amusing to see so simple a matter so hotly discussed. Some, who ought to know, after the government nomination said he accepted. Others declared he only did so conditionally. Others that he declined until he could see whether the Faculty would be unanimous. It is of little consequence. The general belief now is that we are to have the great master, but still a good many will retain their doubts until he has begun to lecture, for they say, in the present condition of things, it is folly to take anything for granted.

The frequency of echinococci in Iceland has for a long time attracted attention, and should any of your readers feel interest in the matter, they will find it carefully summarized in the *Archives Générales de Médicine*, in the form of a French version of the memoir of Dr. Finsen, who is regarded as an authority.

The accoucheurs have always some pretty little debate on, and their views on even practical points are constantly at variance. What wonder then at the theoretical notions proposed and discussed? The Academy has given much attention recently to the subject of peritonitis, *apropos* of the views of M. Guérin, who thinks that the disease arises from the access of air to the interior surface of the uterus, and who proposes to treat it by means of an air-pump. This is the rough notion advanced in a really clever paper, founded on one successful case, and it has set the Academy by the ears. M. Guérin (to give a little fuller account of his views) thinks that after normal labour the os uteri closes and the whole organ retreats to the upper part of the pelvis, so that the surface to which the placenta adheres becomes, so to say, a subcutaneous wound. When the uterus does not thus retreat nor the mouth close, the air finds a ready access, and the wound is no longer a subcutaneous one. But, more than this, M. Guérin says he has found decomposing fluids in the Fallopian tubes, and he believes that these organs actually suck up such fluids, and thus give rise to disease. His treatment therefore (by a tube attached to a suction machine) reverses the course of these fluids, and he has thus removed both fluids and gases. I have seen no one yet who intends to try the practice which was pretty smartly criticized by some of the most able authorities. It was, of course, at once pointed out that when the uterus is full of gases, such an action of the tubes has not been observed, *e.g.*, cases of putrefaction of the fœtus. So it was that the action of the cilia of the tubes is unquestionably downwards. It was doubted by most whether the strongest force of a suction apparatus could produce any effect on the tubes, and various other objections that will occur to the reader were taken to M. Guérin's views, which do not seem likely to make much progress.

The use of arsenic in phthisis, which I named in a former letter, seems much more likely to be generally tried. Not a few seem struck with the idea, and as all practitioners have too many opportunities of treating phthisis, some will be ready to try any reasonable plan or method which promises something, and does not seem likely to aggravate the disease.

As ovariotomy continues to be so interesting a subject to English surgeons, I may name the pamphlet that M. Kœberlé has lately brought out, detailing the results of his sixty-nine cases. The great Strasbourg surgeon has been successful in two-thirds of the cases in which he has operated. Like all ovariotomists of acknowledged eminence, his successes have been gradually improving. If we take his last twenty-two cases only, it is found that only five have died—a proportion that aptly illustrates the great improvements that have been lately effected.

The unaccountable disappearance of a Professor at the Sorbonne, who left the laboratory in a sudden manner, excited a good deal of conjecture at the time; but there is a disposition to conceal everything, which prevents the matter being so fully elucidated as might have been expected.

Notes on Current Topics.

Education.

THE subject of education generally is at the present moment confessedly one of the most important to the nation, and is likely to occupy shortly a large share of the attention of our leading statesmen. So, too, that of medical education is one that more urgently presses every day, and on which the profession, as a whole, cannot bestow more attention than it deserves. We direct the special notice of our readers to the series of articles publishing in our columns in which the subject is treated in its various aspects by a writer who has devoted much attention to it, and whose views ought to be carefully considered by everyone who makes any pretence to understand it. We consider we are doing public service in giving so much of our space to an exhaustive elucidation of this writer's opinions, and we invite the profession to a careful consideration of them as expressed in this series of articles.

Official Reform.

IN the cry that has been lately raised for official reform, we notice one demand that will receive the support of the whole profession, viz., the proposal to appoint a Minister of Health, to whom should be committed all subjects relating to the physical welfare of the community. Had the profession secured adequate representation in Parliament, it is impossible to suppose that the idea of a Minister of Health would seem so far from becoming a fact as it does now. Medical men ought to take an active part in politics. Then they might aspire to see one of their number become the Minister of Health.

Scarlet Fever.

OUR columns have lately borne ample testimony to our desire to give due prominence to the modes of preventing the spread of epidemics of all kinds. We have further treated freely of scarlet fever, and afterwards of its management when it appears in schools. The Registrar-General has lately called attention to the views of Dr. William Budd, of Bristol, and the *Times* even has given its space to a reprint of a communication by that esteemed physician. We may, therefore, recur to the subject, *apropos* of Dr. Budd's opinions. In respect to treatment, we should say he lays much stress on inunction, as that helps to prevent infection by the oil enveloping the particles of desquamated cutis which are the most important source of danger. Our readers will need no enlightenment on the plan of inunction, which has nothing novel in it, but which to certain patients and households will always be repugnant. We believe that the objection to it as a "nasty" process, which has often met us in practice, is the main reason it is not more frequently employed. It is by no means easy to remove such a prejudice. The other directions offered by Dr. Budd are much more suitable for public attention than his mode of treatment, of which only professional readers can be considered capable of judging. Here is the summary of these precautionary measures:—

"1. The room is dismantled of all needless woollen or other draperies which might possibly serve to harbour the poison.

"2. A basin, charged with chloride or carbolate of lime, or some other convenient disinfectant, is kept constantly on the bed for the patient to spit into.

"3. A large vessel, containing water impregnated with chlorides or with Condy's fluid, always stands in the room, for the reception of all bed and body linen immediately on its removal from the person of the patient.

"4. Pocket-hankerchiefs are proscribed, and small pieces of rags are used instead for wiping the mouth and nose. Each piece, after being once used is immediately burnt.

"5. As the hands of nurses of necessity become frequently soiled by the specific excreta, a good supply of towels and two basins, one containing water with Condy's fluid or chlorides, and another plain soap and water, are always at hand for the immediate removal of the taint.

"6. All glasses, cups, or other vessels used by or about the patient are scrupulously cleaned before being used by others.

"7. The discharges from the bowel and kidney are received, on their very issue from the body, into vessels charged with disinfectants."

Those desirous of further materials for advice will find them in abundance in our last few months' numbers.

London University.

THIS institution seems to have made up its differences with the *Times*, or rather that powerful journal has made the *amende honorable* for its treatment of the scientific University. The election of Mr. Lowe as its member has so far conciliated some one in the *Times* office that since then the Pass Lists, &c., have, to the astonishment of some, appeared as University intelligence, with the news of the same character from Oxford and Cambridge. We have often heard London graduates complain of the slight shown by the *Times* in systematically excluding this news from its proper column, as if to show its opinion that the elder Universities were better. Now it has obediently elected the nominee of the *Times*, and he has become Chancellor of the Exchequer, a sufficient advance has been made to entitle the younger University to the same honour as its sisters.

A Nuisance Less.

EVERY judgment given against a nuisance is a benefit to the public, and assists in putting down others. The first time that VICE-CHANCELLOR JAMES took his seat there came before him a case in which it was complained that the defendant collected night-soil from privies, and carted it to some works within 200 yards of plaintiff's house. To the stench that reached his house the plaintiff attributed inconvenience and ill-health, and thought scarlet fever in his family had arisen from it. The affidavits of the other side declared that pains were taken to disinfect by charcoal and lime, and that the nuisance, if at all perceptible, had been much exaggerated. We are glad to chronicle that the judgment was in favour of the right to have our sanitary condition kept unspoiled by others, Without hearing a reply the new Vice-Chancellor said :—

> "The plaintiff's case is, that night after night the defendant has been in the habit of carting large quantities of filth and offensive matter to the sheds about his dwelling-house, where it is subjected to a disinfecting process previously to its being taken to the Falcon Manure Works. He swears that night after night he suffers from a most nauseous smell which is occasioned by the operations of the defendant, and he has brought two or three witnesses in confirmation of his statment. To this case no answer has really been made, unless, perhaps, by the affidavit of one witness who simply says that on two several occasions he has taken a circuit of 40 yards round the defendant's premises and failed to discover any nauseous smell. But no explanation whatever is given of the circumstances under which these visits were made, or anything stated to meet the plaintiff's evidence. It may be that the plaintiff has exaggerated the effect of the nuisance in attributing scarlet fever to it ; but this exaggeration is really not material, nor can it have the effect of disentitling him to relief. He is entitled to the enjoyment of pure air by night as well as by day, and being of opinion upon the evidence before me that his comfort has been seriously interfered with, I must grant him an injunction unless there is something upon the balance of convenience and inconvenience to induce the Court to withhold it. But in the present case I can see no inconvenience that will result to the defendant's counterbalancing the benefit to the plaintiff from granting the injunction."

Medical Club.

THE members of the Club and the profession generally are informed that it has been decided to hold a series of "house" dinners at the Club during the present season. The next dinner will take place to-day (Wednesday), at 6.45, under the presidency of Sir Charles McGrigor, Bart. The price of the dinners has been fixed at five shillings, exclusive of wine. Members may introduce two friends each (not necessarily members of the Club), and if intending to dine are requested to leave their names and those of their friends at the Club-house, or to inform the steward by letter at least two days previously.

Ink.

THE "liquor sanguinis" of literature—ink—has never been as pure and agreeable a fluid as it ought to be, considering how necessary its cordial co-operation is to pleasant writing and profitable reading. Can we not easily imagine that a sudden infusion of gall into the placidity of a leading article may result from the passing annoyance of a smudge in the ink-bottle? and how hard it must be to *do* jokes for the comic journals when your ink will insist on either issuing from your pen in horrible blobs, or else leaving no mark at all.

At last all this is changed. No longer is the leader-writer to be "condemned rash rancour to instil," in having to pen his phrases in uncompliant mud. A new ink, called dichroic, has just been discovered and brought out by Messrs. Bewley and Draper, of Dublin. We must inform our readers that the black matter of ink—the tannate of iron—is not perfectly soluble, but is merely suspended in the water; of course, therefore, it sinks to the bottom of the bottle, and sooner or later makes a sediment. Sulpho-indigoic acid, or solution of indigo in sulphuric acid, is sometimes added to ink on this account, because it gives perfect solution to the tannate of iron; but then the evil of corroded steel pens exceeds the former difficulty. The "dichroic ink" is, we believe, a strong extract of logwood. It is a perfect solution, and therefore leaves no sediment. It is free from acid, and does not corrode the pen. It runs freely and easily, and without greasiness from the pen's point. It becomes black in a few seconds, sinks into the paper so rapidly as seldom to require blotting-paper, and is more indelible than ordinary ink. Against this catalogue of virtues, for its possession of which we can vouch, it has the small demerit that on flimsy paper it is inclined to penetrate too rapidly and show on the other side.

The Bombay Medical Retiring Fund.

THE report of Mr. Browne, to whom the investigation of the finances of the Bombay Medical Retiring Fund had been confided, is such as must gratify the expectant pensioners of the Fund. He considers that certain classes of the annuitants may have their pensions raised to £300 a year from 1867, and suggests that pensions of £160, £200, and £240 may be granted annually for the future.

The Reform of the Medical Council.

WE observe that our contemporary the *Lancet*, in its leader of the 23rd ult., recognizes the plan of reform to which we devoted much attention during the Parliamentary elections, and which it then ignored, apparently for no other reason than that its originator was a candidate for Edinburgh and St. Andrew's University. Whether his mode of retirement from the contest, or the fact that his health has compelled Dr. P. James to pass another winter in the South of France, has induced the *Lancet* to do justice to his proposal, we may readily believe that that gentleman will be glad to see the journal in question willing to discuss the plan of reform to which he has given his attention, and for which we hope he may yet be able to labour.

Assistant-Surgeons at Netley.

We understand that it is probable that a number of Assistant-Surgeons will be sent into Netley Hospital for service during the forthcoming summer. The supply of medical cadets who have hitherto discharged the hospital duty is, as our readers are aware, cut off by the abrogation of the February Competitive Examination, and it thus becomes necessary for the authorities to make other provisions for the care of the invalided soldiers, who are always drafted into Netley Hospital in increased numbers during the summer. It is believed that the Assistant-Surgeons to whom this duty will be assigned will be those who have not yet passed the Promotion Examination, who will thus enjoy the doubtful advantages of a second probation. Whether it is intended to reduce their payment to the Netley rate we are unable to say.

Medical Waistbands.

While the conflagration raged in Rome, Nero fiddled. While the very existence of the Army Medical Service is in debate, admissions to its ranks are suddenly barred, and rumours of sweeping curtailment and degradation in rank are in every mouth, the representatives of Jack-a-Dandyism in the service are in a condition of effervescence about their belts. The military Tomtits, combatant and noncombatant, are hot in the dispute as to which is to have the distinction of an extra feather in his tail; and, meanwhile, the hand of the marauder is in the nest of each alike.

Whether the Assistant-Surgeon's Belt is to be black, blue, or yellow, is a matter of the most contemptible indifference, and may be most cordially assigned to the Tailoring Reformers who have so long amused their little minds at the expense of the British soldier. Let wise men make sure that the belt shall encircle a brave soldier, a proficient surgeon, and an honourable gentleman, and we make to the man-milliners of the service a cheerful concession of its shape and colour.

The Tuebrook Private Asylum.—At the last Kirkdale quarter sessions, Dr. Owen, the medical superintendant of the Tuebrook Private Lunatic Asylum, applied for a renewal of the licence to that institution. Mr. J. A. Tinne, one of the visiting justices, moved that the application be granted, and stated that he had recently visited the asylum, and was much pleased with the order which prevailed, and with the efficient way in which everything connected with the establishment was conducted. He had never seen it in a higher state of efficiency and order, and it reflected credit upon Dr. Owen. The same sentiments were entertained by the visiting justices generally. The application was unanimously granted.

In Dr. Henry G. Wright the profession has lost not only an amiable and accomplished physician, but a very talented literary gentleman. It was he who first instituted the "Annotations" of the *Lancet*, and imparted to them that wit, grace, and charm, which, since he ceased to contribute them, they seem to have lost. His intimacy with the late editor of the *Saturday Review* accounts for certain articles that attracted notice in that always pungent journal.

A request having been made by Mr. Arthur Arnold, that some acres of the Lambeth Palace grounds should be given up for the purpose of public recreation and sanitary improvement, the Archbishop of Canterbury has written to say that the subject is still under consideration.

The depressed state of the funds of King's College Hospital has led the Vice-Chairman of that institution to appeal to the small-sum system, and to solicit every householder in his neighbourhood for help according to his means. He recommends the plan to every unendowed hospital in London.

It is not unlikely that Professor Symes' labours in the Medical Council may be continued, notwithstanding the change in the representation. There seems a disposition to invite the learned Professor to the Presidency which will shortly be vacant.

Extraordinary statements were made at a meeting of the Holborn Guardians last week. The committee appointed to inspect the pauper lunatics sent from the union to the asylum, reported that two persons had been sent to the Salisbury Asylum who were found to be perfectly sane. The union surgeon who accompanied them, it was said, confirmed their report.

The *Press and St. James's Chronicle*, in announcing that Mr. W. Blanchard Jerrold has been commissioned by the Government to inquire into the condition of the pauper asylums of Europe, says:—"The object doubtless is to gain information as to how other nations deal with the great difficulty of increasing pauperism."

Baron Rothschild, of Vienna, has just given the munificent sum of 200,000 florins for the erection of a Jews' Hospital, which is to contain 100 beds.

It is reported that the buildings and grounds of the old Magdalen Hospital are to be converted into a circus for equestrian performances. The last of the inmates of the hospital were, a few days since, transferred to the new and more spacious edifice at Streatham.

On Thursday evening last a very successful amateur dramatic performance was given at the Queen's Concert Rooms, by the resident medical officers and students of St. Mary's Hospital, Paddington, in aid of the charity. The performance was well supported by a crowded and fashionable audience, as was also the ball for the same object, by which it was succeeded.

The legacy of Mr. Clarke, jun., of Mile end, to the Glasgow Infirmary will amount to no less than £20,000, and that to the University to £30,000.

At the meeting of the Harveian Society to-morrow (Thursday) evening, a paper will be read by Dr. F. Cock on "Intestinal Obstructions."

DR. RUDOLPH SCHMITT (pupil of Kolbe), the well-known lecturer on Chemistry at Kassel, lost a few days ago one of his eyes, by the explosion of a bottle of chemicals which he held in his hand.

THE Lord Chamberlain has forwarded a circular to the managers of all the theatres on the impropriety of costume of the ladies in the pantomimes, burlesques, &c., which are now being performed in some of the metropolitan theatres.

AT a meeting of the Lambeth Vestry, the members of committee and the medical officer, who visited the courts and passages in that neighbourhood of which complaint had been made in the newspapers, stated that, "notwithstanding the defective state of the drainage of these places, and the dirt that prevails there, the poor people obliged to live there were free from infectious disease; but they considered that steps should be taken as soon as possible to effect the necessary improvements."

THE examination of candidates for commissions in the Medical Department of the Army, appointed for the 8th February, will not be held, there being no vacancies to fill up.

THE fifth case of hydrophobia which has ended fatally at Halifax during the last few months is reported in the *Leeds Mercury*. The man, bitten several months ago, has lately died. Considerable excitement prevails.

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. X.

MY diagnosis of Mr. Snigby's case, and the opinion I mentally pronounced upon it, was incorrect, for Mr. Snigby invariably spoke with energy, and displayed on all occasions a large amount of muscular "gush," which was considerably augmented whenever he touched on the subject of his "affliction."

Mr. Snigby reassumed the semi-prone position, and detailed to me his symptoms as they had just manifested themselves to him. "At half-past one," he said, "Fata gently raised me from this troubled couch and caused me to float round and round the apartment, sometimes tilting me against its walls, at other times bumping me against its ceiling, and ultimately compelling me to move with considerable speed towards the window-sash; and the moment I believed myself about to violently urge a passage through, or to get seriously concussed and damaged in the attempt, I became agreeably conscious and happily disappointed to find that I had passed to the external world, not only unscathed, but without experiencing the ordinary sensation of contact with, nor of resistance from, the vitreous barrier.

"Now I appeared to be quite aware of the charm exercised over me by Fata, and attempted again and again to move and to throw off the burden that oppressed my thorax, and thereby to free myself from her power and her influence; but I failed in the endeavour, and being in the 'raw atmosphere' without doors, I seemed to move with considerable velocity—and without the trouble of a single muscular exertion on my part—over a very large section of the entire globe. Nor was my altitude from the earth extraordinary; but it was nearly uniform. And as I passed over villages, forests, cities, and seas, I became seriously apprehensive of instant demolition from direct contact with spire or tower, tapering mast, tree, rugged rock, wall, or other insurmountable obstacle; and just as the inevitable collision was about to be evinced, the obstacle appeared to vanish, and astonished and surprised I invariably found that I had passed the difficulty, and was already beyond its power and its influence.

"The sky appeared to display a hundred moons and a million stars, throwing their rays in minute pencillate thread-like streaks, and in broad and silvery ribbon-like bands, that formed a trellis-work on the earth, pale, chaste, and indescribable, giving to each country, and city, and sea over which I floated its tint or the *cast* of feature to which it was legitimately entitled. Yet whether I passed over the burning plains of Sahara, took a turn round the North Pole, or hurried within the limits of our more favoured latitude, *my* temperature was unchanged; and, strange to say, during the lengthy journey not a single sound disturbed the stillness—silence, calm, serene, and dignified, solemn and uninterrupted, filled with mystic grandeur the vast globe.

"But the peculiar light yielded by these moons and these stars, was at times dull, heavy, unanimating, dreamy, and lifeless, robing the horizon with sober, stately, liquescent phenomena, giving momentary snatches of chameleon-like lines to the earth over which I passed, with such eccentric velocity, and displaying through gloom and ethereal vapour, a universe in the awful sublimity of still and silent life—weird-like, mythical, and incomprehensible—the recollection of which will ever be to me as vivid and as undying as very life itself.

"I continued to make every possible effort to move in my bed in order to dispel the illusion, and ultimately considered I had accomplished the object aimed at, for I left it and paced my room with firm and unfaltering strides for some time, and then deliberately shifted the window blinds aside, and looked out into the murky street to behold the flickering lights in neighbouring lamps burn with a ghastly glare that appeared to denote Fata's influence even on them. I heard the click-clack of horses' hoofs, and the splashing of wheels from night and other vehicles as they passed along. I distinctly caught, too, the sound of voices outside, as if there had been a midnight brawl beneath my bedroom window, and the voices grew loud or dwindled into simmering whispers as the wind blew stiff or gentle against the window panes, whereat I stood. Then all was silence again, save the troubled wind's plaintive wail through chink and through crevice.

"I considered myself more or less under the power of Fata even yet, for I could not rouse myself nor assume my ordinary habits of thought nor of action, but continued in a dreamy indescribable state, such as I never before experienced. Determined, however, to free myself from my tormentor, I left the window side, paced the floor as heretofore, tried to articulate, to cry out, and to pinch my flesh, in order to arouse and to re-vitalise, as it were, my strange state of body. I wretchedly failed in these endeavours, much to my chagrin, whereupon I strode to my bedside, and took a seat there, fully resolved to make a bold stand and to see it out with Fata. *Pro Hâc Vice.* Well! How long I remained in *that* posture I know not, nor how I left it, nor how or when I came here—back again to the original position out of which Fata raised me

—I am unable to say. All I *do* know is this—*that here I am!!—in bed!!!* Sir, I have described my last symptoms, do you understand?"

I expressed my obligations for the clear and lucid statement made by Mr. Snigby.

"Sir," continued that gentleman, "you have my statement, what remedy do you propose? But remember—I have sacrificed much time and much money in my vain search for riddance of Fata. I have swallowed to the very dregs the *contents* of every known Pharmacopœa. I have been galvanised, mesmerised, electrified, and animal magnetised. I have been Turkish bathed and chloroformed. I have been laved in spiced wine, old Tom, Roman punch, and Irish whiskey. I have tried every water, from the Caspian to the Shannon, from the Missouri to the Tweed, from the Red Sea to Margate. I have been 'friction rollered' by machinery patented and erected on my own special account. I have sought relief in nearly all geographically acknowledged climates, and at all seasons. I have 'taken in' oxygen, tried chest-expanders, practised elocution, poised dumb-bells, and turned a mangle. I joined a gymnastic class, a fire-escape corps, and became a railway express engine-driver on the Nick or Nought Line (Limited). I was a deputy sheriff's assistant, a relieving officer, a special constable, and a collector of old coins and ancient pictures. I ducked in a diving-bell, went up in a balloon, and rode a steeplechase. I wrote verses, tried painting, designed model dwellings for the industrious classes, signed the rate-in-aid protest, took the chair at a friendly lead, skulled to Putney for *no* wager, lost at the Derby, went into politics at high pressure, and finally became moving director of the Patent Eustachian Tube Company (Limited). Sir, in a word, I have done everything that has been recommended to me; all, all have failed."

My patient was quite exhausted. His long journey, followed so closely by his long speech, were sufficient to account for this; so he paused, looked at me with suffused eyes, ere he said, "Sir, what do you recommend?"

"Rest for the present," I replied, "you are tired, Sir."

"Sir, pardon me, but do you really consider that the object I had in sending for you was that you might prescribe rest for *my* complaint?"

I begged not to be misunderstood by Mr. Snigby.

"Then prescribe; pen, ink, and paper lie opposite—*can* you?"

During my lengthy visit to Mr. Snigby I unquestionably had very serious doubts as to his mental condition, independent of those that his night-cap suggested; but when he finished this last speech, and appealed to me in such a manner as to leave it quite out of my power to parry with him, and to finally escape from his presence without prejudice to my professional intelligence, I asked him if he had been troubled by Fata ere he first commenced to use the night-cap?

"Sir, the night-cap," replied Mr. Snigby, "was prescribed by an eminent physician as a cure for my complaint."

"Pardon my inquisitiveness, but please say if you really have taken much medicine."

"Sir, the Pharmacopœas all," replied my patient.

"You are pretty comfortable in circumstances, eh?"

"Sir, yes, my means are good."

"Live alone, Sir, see much society?"

"Sir, I live nearly alone; I *have* seen much society, but no cure followed *that* prescription."

Mr. Snigby became now quite composed, and spoke in a most rational manner, giving me distinctly to understand that he was temperate, very studious, affable, and good-tempered in ordinary life; but when troubled by Fata lost all control of his faculties, and determined on all occasions that she troubled him to try and to conquer the beast.

I mused and listened for some time.

"Sir, write me *your* prescription," he again said.

"My prescription will scarcely be a medical one; but as you insist on having it before I give your case the consideration I should wish, you must excuse its abruptness;" and as I spoke I moved towards the table, whereon rested pens, ink, and paper, and wrote it.

I folded the slip of paper note-fashion, placed it in his hands, bid him good morning, took up my hat and hurried from the apartment in a twinkling; and ere Mr. Snigby recovered from the surprise my sudden and unexpected movements caused him, I was again surrounded by my "floculent" envelope, *trying*, unsuccessfully, however, to provoke the gentle goddess.

I append copy of the prescription:—

Die Mercurii, 10·5 a.m.
Mr. Snigby.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As there is a good deal of agitation at present about Poor-law medical officers and their appointments, perhaps a short account of the treatment accorded to me by the Clun Board of Guardians in Shropshire, the Poor-law Board, and one or two of my medical brethren in this town, may strengthen the reasons why the Central Board should be completely reorganised, and a new Board composed of at least one-half medical men, be constituted; but I should like to know who are the members of the Central Board, and how often they attend? Are we to have the finger of scorn pointed at us eternally? Are we to be told we must do as they wish; that if any member of a Board of Guardians finds fault, or has a quarrel with a medical officer, or even happens to be offended slightly, poor Medicus is to be kicked out of his appointment, his bread taken away, and interest used to mar his private prospects in practice? Oh, Sir, the day will soon come when we must be up and doing; when we must make a stand against such *tyranny*, for 'tis nothing else. Are there any of my medical brethren like me? From what I write they may judge.

In the beginning of 1863 I purchased a practice in this town from a Mr. Hughes, and I may, at some not very distant period, tell you how I fared, and give you copies of his and his agent's letters; if they don't interest, perhaps they will amuse. He did not resign his parish appointment, according to contract, but held it, as he said, for me, for about three months; he was then served with a notice to resign such by the Board of Guardians, which he did. I accordingly applied, as I had been doing all the work, Mr. Hughes having gone to reside about sixteen miles by coach-road from here. In the meantime, Mr. Brook, the medical officer of the workhouse, who had been afflicted with paralysis for years, was thrown out of his gig, and received some severe injuries; I happened to be near at the time, and attended him; he had profuse hæmorrhage from the middle temporal artery, and was otherwise exhausted. I did all his work for nearly a month, and he told me he would have to get an assistant, but should not think of opposing me for the Union appointment, which I ought to have, as I had purchased Mr. Hughes' practice; shortly after he got an assistant, and this gentleman got the appointment, and a few days afterwards went up to London and passed the Hall! However, to crown all, he only stayed for a few months, and the Board of Guardians sent for me, and offered me the appointment, which I accepted in November. Things went on pretty smoothly, though I had to put up with a good deal from one or two of the guardians, who were continually bringing charges against me, *not one of which they ever sustained.* In March, 1867, a Dr. Lemon came from Welshpool to become a partner with Mr. Brook, or else buy his practice, which he has done I cannot say. I met this Dr. Lemon on the day of election at the Board-room; here he came up to me, introduced himself, said he had taken Mr. Brook's practice, and hoped we should get on well together. "Why," I said, "I have been told you have come to get my appointment." "Nothing of the kind," he said, "Dr. Lane; I always do everything honourably; and if I had applied for your appointment I should have told you. Besides, I am only looking for Mr. Brook's, and I hope you won't oppose me." "No," I said, "I have one appointment, and that is plenty." Well, imagine my astonishment, when he came out of the Board-room in ten minutes afterwards, and coolly said, "Oh, Dr. Lane, the Board have given me your appointment, and Mr. Brook keeps his for the present!"

One Sunday I met Dr. Lemon. "Well," he said, "I can't understand you reporting Mr. Brook; he will hold his appointment in spite of you, Sir, and you shall be shown up in the medical papers for this." "Well, well," I answered, "go on; you can help him, I dare say, and I shall only be too happy to be called to an account by you or him; it is all I require." However, up to the present time I have never seen anything about it in print. The Poor-law Inspector said I had proved my charges in a most satisfactory manner, and I have been told Mr. Brook was requested by the Poor-law Inspector to resign. However, he held his appointment up to March 1868, and then his parish was given to Dr. Lemon, and the Union was also given to Dr. Lemon at the same time, *without being advertised.* Was this legal? I wrote to the Poor-law Board about the matter, but they did not know what to do. Thus, at the present time Dr. Lemon is holding appointments which have always been held by two, and sometimes three, medical men, the acreage of which is 30,501, the population 5,379, and the salaries £112 10s., exclusive of extras—which has been nearly £100 some years; and this Dr. Lemon calls his highly professional conduct! I had a letter not long ago from the Poor-law Board in answer to one I wrote, and they said they were in communication with the Board of Guardians here, so that even at the present time Dr. Lemon's appointment to the various parishes and union workhouse has not been sanctioned. On the 7th of December, 1866, I signed my contracts with the Board of Guardians of the Clun Union as Medical Officer and Public Vaccinator—one contract requiring one month's notice, the other twenty-eight days. They took my appointment from me, as Medical Officer, without serving me with the month's notice, as specified in the contract, but they gave me the twenty-eight days' notice for vaccination contracts! according to agreement, their excuse being that I had asked for re-appointment, and that annulled my contract. Why did it not release vaccination contract as well? Remember this was about the middle of March, and on the 2nd of April their Clerk wrote to the Committee of the Bellaghy Dispensary, Magherafelt Union, County Derry, Ireland, of which I append a copy:—

"Clun Union.

"Day of fortnightly meeting, every alternate Friday.

"The next meeting will be held at Bishop's Castle, on the 12th day of April.

"*Clerk*, FREDERICK PARDOE, Bishop's Castle."

"Bishop's Castle, April 2nd, 1867.

"DEAR SIR,—I should be much obliged if you would inform me why *John William Lane* left your dispensary. as he is a Medical Officer of one of the districts in the Clun Union?

"Yours truly,

"FREDK. PARDOE, per H.S.N."

When they appointed Dr. Lemon to the districts I held from the 25th day of March, how could I be one of their Medical Officers!!! When I produced this document at the Board on the day of inspection into my charges against Mr. Brook, the Inspector told me to keep it, as it might be of use to me at some future time; and he told them I was virtually one of their Medical Officers, and that they ought to have given me notice, as my contract did not specify any particular time as to the duration of such contracts, and that he also considered I had been very badly treated, and that I had always repudiated any charges that had been brought against me. I have been strongly advised to take an action against the Board of Guardians for damages for illegal dismissal and loss by such, but as I have a large family, and no means to throw away upon law, I have refrained from doing anything. I should like the sound opinion of some of my medical brethren on these points, and will, if wished, forward all copies of letters on both sides for publication. The following is the answer to the aforesaid official document:—

"Bellaghy, 6th April, 1867.

"SIR,—In reply to your note of 2nd inst., respecting Dr. Lane, I beg to say he left this dispensary upon his own resignation, and very much to the regret of our Committee and the feelings of the inhabitants. I had pleasure in forwarding to him a complimentary address signed by the chairman and members of our committee.

"Your obedient servant,
"I. HILL,
"Hon. Secretary, Dispensary.

"To F. Pardoe, Esq."

One of my friends, W. J. Clement, Esq., M.P., wished me to join the Shropshire Branch of the Medico-Ethical Society, and bring this matter fully before them, but as yet I have done nothing in the matter; this is my first step. The case, in my opinion, stands thus: the Board of Guardians appointed Dr. Lemon to the different parishes; the Poor-law Board won't sanction such, and wish to know why I have been removed, the answer to which I have not heard. I have a few staunch friends in the Board, but they are in the minority, and some are afraid, *as they have told* me, to speak their minds!!! It is utterly impossible for one medical man to do justice to the poor of so many districts; for in 1864, when the Chairman of the Board asked me if I would take what Mr. Brook held, I distinctly refused, as I knew I could not conscientiously do the work: but I daresay Dr. Lemon thought, when he got my appointment, he would also quickly walk into my practice, but he has found out his mistake by this. What has become of the *Lancet* Commissioners? Would they pay the Clun Union a visit they would find material enough to make a small volume, I fancy. When the Board found Mr. Brook had to resign, they gave all to his successor. Only that it would take up too much of your valuable paper, I could fill its pages over and over again with matter relating to this. I hope this may come under the notice of the "Poor-law Medical Officers' Association" of London.

I remain, Sir,
Yours faithfully,
J. W. LANE, M.D., L.R.C.S., &c.

Bishop's Castle, Shropshire,
January 6th, 1869.

INFANTILE TETANUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Perhaps the following case of that very incurable disease, infantile tetanus, may be worthy a place in your columns. I was called on the 13th inst. to see a male child, aged eight days; the parents were healthy, but the mother had lost her three previous children all at the time of dentition. The body was in a state of opisthotonos, and exacerbations of the spasms occurred about every fifteen minutes. The masticatory muscles were not affected, showing the impropriety of the term, "trismus nascentium." The umbilicus was in a healthy condition. My father saw the case in consultation with me, but our treatment was not successful. The child lingered on to the ninth day. Twenty-four hours after death I removed the spinal column, and sent it to Dr. Mapother. He, having examined it carefully, states:—"The space between the laminæ of the vertebræ and the dura mater in the lower dorsal and lumbar regions was filled with extravasated blood. The arachnoid was highly vascular and dull, and upon it in three places there was greenish lymph effused. The cord, when divided transversely in several places, exhibited vascular points. The nervous matter was not sufficiently recent for microscopical examination.

I am, &c.,

Jan. 23, 1869. JAMES W. JOHNSTONE, L.R.C.S.I.

Literature.

It does not often fall to the lot of medical reviewers to exercise their judgment upon a volume of this kind,[1] still less so when the work emanates from the pen of a member of the profession. The medical man is decidedly the last to be suspected of sentimentality; the very nature of his work is so diametrically opposed to it, and the fatigue of hospital or private practice is usually so great that he has few opportunities to foster flights of fancy, time to indulge in the lay of the poet, or the fiction of the novelist. Happily, however, there are exceptions to this rule of incessant toil, as demonstrated by the above book. Volume upon volume of medical literature flow in upon us, and, judging from inference, in this multitudinous array there must of necessity be but little that is new. We see no reason, to use the author's own words in his preface, why the lighter branches of literature should not be resorted to in leisure moments, "as a divertissement to thought, a solace in care, or a mental recreation to relax the mind when overwrought by sterner studies, or over-burdened with the weight of professional responsibility." Dr. Evanson, in his introduction to the volume under notice, informs us that the failure of health compelled him to quit the field of his professional calling some eighteen months since, and to journey to the South of France, where he was enabled to complete the work which had long been one of the objects of his ambition. After this admission, we can scarcely understand why "a feeling of indifference" should possess the author as to the probable reception of his work. Dr. Evanson's name is not unknown in medical literature; and he need not be ashamed that he has sent the present volume through the press with his name attached, although it is of so totally different a stamp.

And now as to the general contents of the work. The first is a poem of somewhat irregular metre, entitled, "Nature and Art," occupying about a hundred pages, being an elaborate description in verse of the opening of the International Exhibition of 1862, its contents, the closing ceremony, and the *morale* of Exhibitions in general. The remainder of the volume is a collection of occasional verses and elegiac stanzas in memory of departed friends, some of whose names have become immortalised in the annals of medical greatness.

Some of these lines bear the impress of a poet of no mean order; thoughts here and there may be found breathed in language at once elegant and exalted, while throughout the whole the author seeks to elevate the noble science of medicine, and the members of the profession who follow its doctrines, and of which Dr. Evanson himself is such an enthusiastic disciple, to the highest pinnacle of social and moral importance. True, like most poets who essay the art for the first time, the author is sometimes guilty of faulty metres and inharmonious rhyming, such as "mind and joined," "worth and forth, &c.;" but these are minor errors, errors which are sometimes committed by writers who have earned a name, and must not therefore be severely criticised, or allowed to interfere with our expressions of the general excellence of the book. It is, moreover, elegantly got up, and would doubtless prove a very acceptable gift-book, particularly at the present season.

Our space forbids extensive quotations, but we will give one short extract from an elegiac stanza, written in memory of Surgeon Llewellyn, of the "Alabama," whose heroic conduct on board that notorious ship was the subject of universal admiration by the press and the public some four and a-half years since, as a specimen of the author's powers of versification:—

. . . . .

"A glory in youth or in age,
To succour the sick and the dying.
But bravest before all the brave,
He cared not his own life to save;
He cared for the wounded and dying."

We would also commend to the notice of those of our readers who care for this kind of literature, "The Outcast," "Man and Monkey," in which the author sarcastically disposes of the theory recently set up by one of our distinguished professors, as to man's relation to the gorilla; and "Medicine," which is a short poem inscribed to Professor Stokes, of Dublin. Some of the others are equally good, but of a lighter class, and would not be of the same interest to the generality of our readers as those we have mentioned.

DEPUTATION TO THE LORD LIEUTENANT OF IRELAND.

A DEPUTATION of the King and Queen's College of Physicians in Ireland waited on His Excellency the Lord Lieutenant, on Friday last.

The deputation consisted of—

Dr. Churchill, President; Dr. Freke, Vice-President and Censor; Dr. Apjohn, Professor of Chemistry; Dr. Atthill, Censor; Dr. Banks, Dr. Beatty, Dr. Belcher, Hon. Librarian's Dr. Churchill, jun.; Dr. Croker, Dr. Dwyer, Treasurer; Dr. M. Eustace, Dr. Foote, Censor; Dr. Hayden, Censor; Dr. Jennings, Dr. Johnson, Dr. Evory Kennedy, Dr. H. Kennedy, Dr. Law, Professor, Institute of Medicine; Dr. Jame; Little, Registrar; Dr. Lyons, Dr. Mollan, Dr. Ringland, Dr. Sinclair, Professor of Midwifery; Dr. A. Smith, Professor of Materia Medica; and Dr. Walter Smith.

Dr. Churchill, the President, read the following address:—

"MAY IT PLEASE YOUR EXCELLENCY.—We, the President and Fellows of the King and Queen's College of Physicians in Ireland, beg to approach your Excellency with the expression of our devoted loyalty to her Most Gracious Majesty the Queen, and our cordial welcome and congratulation to your Excellency on your arrival in this country as her Majesty's Viceroy. From the time of our incorporation, in the 17th century, we have always been mindful of the important trust committed to us, and have endeavoured to secure a succession of physicians competent to take charge of the health of her Majesty's subjects. We beg to assure your Excellency that, as it is our duty, so it will at all times be our anxious desire, to afford aid to the Government in any measure calculated to improve and secure the public health."

His Excellency gave the following reply:—

"MR. PRESIDENT AND FELLOWS OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS,—I thank you for your expression of loyalty to Her Majesty, and of congratulations to myself. During the many years since your incorporation, the changes which have taken place in medical science have been great, and discoveries have been made which largely conduce to the preservation of health. In diffusing the benefit of those discoveries your society plays an important parts; and by continuing to send forth a succession of competent and able physicians, you merit the thanks of those to whom the public health is a matter of solicitude."

The deputation then withdrew.

FREEZING.

IN the *Journal de' Anatomie et Physiologie*, Ponchet gives some experiments on the freezing of animals. He denies the assumption of certain physiologists, that there are animals which can survive complete freezing. Numerous experiments showed him that the blood corpuscles undergo a change, which renders them unfit for performance of their functions. The greater the number which have undergone the metamorphosis, the sooner the animal perishes. If we push congelation to one half, the animal will live a long time, because the altered corpuscles are kept out of the circulation by stasis of the blood. As soon as we allow it to thaw, however, the sick or changed corpuscles mingle with the rest of the blood, and the animal perishes.

CHLOROFORM TO THE SPINE IN SPASMODIC DISORDERS.

THE *Pacific Med. and Surg. Journal* says:—As a substitute for general anæsthesia, several writers have suggested the application of chloroform to the spine, by means of strips of muslin saturated with the liquid, and covered with oiled silk to prevent evaporation. A case of traumatic tetanus treated in this way is reported in the *Humboldt Medical Archives* by Dr. Percy L. Rooney, of St. Louis. The patient had tried ice to the spine, and various other means without relief, and the disease was well advanced when the chloroform treatment was instituted. Signal relief, however, was afforded, and comfortable sleep secured for a time. But it appears that the agent was not applied *constantly*, and that the paroxysms were allowed to recur in the intervals of the application; and this, together with the exhaustion which had taken place before the treatment was instituted, rendered the trial incomplete, and inneffectual in saving life.

SURGERY.

TRANSFUSION.

Frese publishes some interesting facts on this subject in Vichow's *Archiv*, xl., (*Allgem. Med. Central Zeitung*, No. 50, 1868.) Experiments have shown that transfusion with the blood of fevered animals produces fever. Frese had made this observation himself, and has now extended his investigations with the following results :

1. The transfusion of small quantities of healthy blood (up to one-tenth of its entire bulk) produced no considerable increase of temperature.

2. The transfusion of large quantities of healthy blood (one fourth to three-fourths of the entire bulk) always caused a feverish elevation of temperature when a corresponding venesection had preceded the transfusion. The greater the interval between the two operations, the more considerable was the elevation of temperature ; but this never exceeded an increase of 1° C.

3. A simple venesection also caused an elevation of temperature ; but this only took place some time after the reduction of temperature, which is the primiry effect of bleeding.

FROST-BITE—TETANUS—PULMONARY EMBOLISM. BY M. MICHEL.

M. Michel had noticed certain affections of circulation and respiration following injuries such as frost-bite or burns. The following case throws some light on the subject :—A young man, aged twenty-two, had both his feet frozen, and also suffered from a paralysis of the radial nerve of the right arm. Symptoms of asphyxia followed, and showed signs of improvement, when, on the eight day after the accident. tetanus supervened, of which he died in twenty-four hours.

The autopsy showed clots in the dorsal veins of both feet, in the internal and external saphena veins, in the right ventricle, and in the fine ramifications of the pulmonary artery. The paralysed radial nerve, when compared with the healthy one, showed a lesion of the medullary substance of the tubes, consisting in a coagulation presenting a curdled appearance, which in some places tended to become granular. It resembled very closely the changes which take place at the peripheral extremities of divided nerve. (*Gazette Medicale de Strasbourg* and *Edin. Med. Journ.*)

USE OF COLLODION TO LIMIT THE EFFECTS OF THE ACTUAL CAUTERY.

M. Voillemier made the following remarks on this subject in a clinical lecture :—All surgeons know how difficult it is to limit the action of the actual cautery, especially if it is wished to apply it to a limited point. The finer the point or the narrower the edge of the instrument, the more necessity there is for having a shoulder of thicker metal close to the edge or point, as a reservoir for the caloric. But the reservoir radiates he at on the neighbouring tissues, and by its nearness, though itmay not actually touch, is apt to cause burns of the first or second degree to a greater or less extent. And this accident is not without importance. It is the cause of the pains which are felt after every application of the cautery ; pains which are severe, may last several days, and the intensity of which is but little diminished by the continuous use of cooling lotions. After some days, the epidermis peels off, leaving the true skin bare often to a very considerable extent beyond the portion (perhaps the *small* portion) which had been completely destroyed by the cautery. These superficial wounds often last for a long time. Attempts are often made to prevent their occurrence by surrounding the parts intended to be burnt by wet rags or pieces of wood. These methods are, however, often ineffectual, and are apt to interfere with the proper performance of the operation. The following proceedings, more simple and more certain, I have used with great advantage for five years : —The part intended to be cauterised being first carefully wiped dry, one or two layers of collodion are painted on. These soon dry, as is shown by the white colour. Then the moment for action arrives ; not sooner, lest the vapour of ether which is disengaged should take fire on the approach of the red-hot metal. This little accident is not important, as it can easily be extinguished, but it is better to avoid it lest it alarm the patient. The cauterization can then be performed as usual. The collodion is at once destroyed at the points touched by the iron, the action of which it does not interfere with ; but it remains unaltered in the neighbouring parts, for which it forms a sort of artificial epidermis. This is very thin, but is composed of pure cellulose,—a body which conducts heat less even than wood, and effectually protects the tissues against the heat radiating from the metal. The operation over, if the collodion be removed, the skin is found white and healthy below it. It is better, however, to leave it, as, by the pressure it exercises, it seems to prevent swelling of the parts. It is unnecessary to cover the burnt part with wet rags, for the patient complains of no pain, as might be expected ; for the parts actually touched by the red-hot iron are disorganised and insensible : beyond these points, the skin is healthy, and not affected by the heat. This plan is very useful in the vicinity of joints, but still more so in the axilla or border of the anus, where the parts close to those we wish to touch are so near, It also enables the surgeon to apply the actual cautery with certainty and safety, even to the neck of the uterus. (*Gazette des Hôpitaux*, No 61, 1868 and *Edin. Med. Journ.*)

LIFE PROLONGED FIFTY-NINE DAYS BY NUTRITIOUS INJECTIONS ALONE.

The following is related in the *Deutsche Klinik*, No. 27, 1868 by Dr. Runge. A patient consulted this gentleman for stricture of the œsophagus in May, 1867. After varying success with bougies and local medications an abscess occured in the cellular tissue of the neck, April, 1868, and completely blocked up the œsophagus, so that not even liquid aliments could be taken. Injections of yolk of eggs, soups &c., were made, the patient being kept perfectly quiet ; and under this treatment alone, he lived from the 20th of April to the 18th of June, a period of 59 days. In the first week the patient got thin, and complained of an annoying sensation of thirst ; in the third week he felt neither hunger nor thirst, nor pain, and was but little thinner. The eighth week an inflammation of the large intestines was developed, and the patient died the week following. Dr. Runge thought that had it not been for this intercurrent inflammation which he seemed to regard as possibly curable, the man's life might have been prolonged several weeks longer. But it strikes us that such would, in all probability, be the result in all cases from this mode of alimentation and that this patient lived to the possible limit of life under the conditions.

LUMBAR HERNIA.

Q. C. Smith, M.D., reports (*Nashville Journal of Medicine and Surgery*) a case of this kind which had existed in a patient from her birth. It was situated in the left lumbar region, and continued to increase in volume until she was 15 years old. The tumour gave considerable pain during childhood, and prevented her from performing any labour or making great exertion. From the period of puberty until she was about 30 years old it was stationary, or it gave no particular pain or uneasiness. Nov. 11th, 1867, she fell from a waggon, dislocating her right ankle and receiving severe injuries upon different parts of the body, by which she was confined to her room for three months. She was disabled or the medical attendant failed to reduce the dislocation. At puberty the tumour was about half as large as a goose egg, which size it retained until the receipt of the injury, when it steadily increased in size and caused considerable pain. It now became about half the size of a new-born infant's head, and had the soft doughy feel common to omental hernia. The patient had suffered greatly from the effects of malaria, in consequence of which she had enlarged spleen and liver. The pressure of the enlarged organs and of the hernia upon the veins leading from the lower extremities caused œdema of the feet and ankles. Antiperiodic medicines were administered, and a supporter was applied to the hernial tumour. Under this treatment she rapidly recovered in health and strength.

Ptyalism.

Dr. **Ahrouheim** (*Deutsche Klinik*, No 35, 1868) presented before the Berlin Medical Society, two cases of chronic salivation in children ; caused by the careless application of ungt. hydrarg. to their bedsteads for the destruction of vermin.

Dr. Beer at the same time called the attention of the Society to a woman æt. 40 years, and unmarried, who had not menstruated in four month and was affected with ptyalism. An acrid saliva continually flowed from her mouth. Evident signs of pregnancy were not present, but most of the gentlemen were of opinion that the sympton was attributable to that cause.

ANATOMY AND PHYSIOLOGY.

WHAT IS NERVO-MUSCULAR PROSTRATION ?

ORDINARILY, perhaps always, the pathological condition in palsy is a lesion of the brain or spinal cord, in their substance or membranes, and it can be readily traced to one or the other of these as the centre whence the disturbing influences flow. Ordinarily, too, the lesion is the result of some ascertainable exciting cause, which points to some particular region as the seat of the lesion. How is it here ? No such " cause " guides us in the solution of the mystery. The brain exhibits no indication of disease or disordered action. The intellectual faculties are all intact. Speech is not disturbed. The will sends forth its mandates as in health, but the muscles in certain localities are powerless to obey. There is no symptom which clearly indicates cerebral congestion or inflammation. If, now, we turn to the spinal cord, we find little in the symptoms present which points to any lesion there. There may be congestion, but it is slight if it exist at all. There is no tenderness of the vertebræ, such as we find in affections of the spinal cord. There is no muscular contraction or spasmodic action of the muscular fibres. There is slight pain and a slight sense of fulness in the lumbar region ; but this may be satisfactorily accounted for by the jolting of the waggon, and the violent contact of that region with the low-backed seat. If, therefore, so general prostration of the muscular system be produced by lesion of the spinal cord, or of its membranes, that lesion, whatever its nature may be, must affect the whole extent of the cord, from the cervical vertebræ to its termination in the os coccygis. Could it exist without some one or more of the pathognomonic symptoms indicating it being present ? Could it thus obtrude its unwelcome face without displaying some of the prominences of its physiognomy ? It may be so ; but are there substantial grounds on which to base such an opinion ? (*Dr. L. C. Butler in the Boston Medical Journ. Jan.* 1869.)

NOTICES TO CORRESPONDENTS.

To **CORRESPONDENTS.**—We would impress upon our numerous correspondents the necessity of making their lectures, Original Communications, or letters intended for insertion, as short as is consistent with the subject on which they treat. We find it necessary to intimate this to our many friends, in consequence of complaints continually reaching us from contributors, who are anxious to obtain an early publication for their papers.

IN deference to the wishes of a large number of our readers, we intend forthwith to devote several columns weekly to *excerpta* from the best British and Foreign journals, in order to keep our subscribers *au courant* with the progress of medicine and surgery in all parts of the world.

A NAVAL SURGEON.—The subject of your letter is under consideration. The author is an M.D., and not as you supposed. It is probable the present will be the last.

DR. WHITE (Macroom).—Macnamara's seventh edition of "Neligan's Medicines, their Uses and Modes of Administration," price 18s., free by post, or 16s. cash to a practitioner. Squire's (last edition) "Companion to the Pharmacopœia," is a good book, price 10s. 6d., but not so good as the former.

DR. BALTHAZAR FOSTER (Birmingham).—The communication will receive immediate attention.

DR. MACCORMAC.—The alteration has been attended to.

"Treatment of Scarlatina." by J. Johnston, M.R.C.S.Eng., received.

DR. COATES.—Under the circumstances you could not be held responsible.

DR. ALEX LEADMAN.—Certainly.

ROYAL COLLEGE OF PHYSICIANS.

THE LECTURES OF THE PRESENT YEAR

Will be delivered at the COLLEGE, Pall Mall East, at Five o'clock on each of the following WEDNESDAYS and FRIDAYS.

GULSTONIAN LECTURES. — DR. J. HUGHLINGS JACKSON, Feb. 19th, 24th, 26th—On Certain Points in the Study and Classification of Diseases of the Nervous System.

CROONIAN LECTURES. — DR. JOHN W. OGLE, March 3rd, 5th, 10th—Regarding Certain Effects of Modifications of Nerve-Influence in Disease.

LUMLEIAN LECTURES.—DR. BARKER, March 12th, 17th, 19th—On Diseases of the Serous Membranes and some of their Results.

(By order of the President),
1869. W. COPNEY.

MENTAL DERANGEMENT.—Orchardstown House, Rathfarnham. PRIVATE ASYLUM. The Patients receive every attention and kindness under the care of Mrs. STANLEY, Proprietress, and her family. Dr. HENRY CROLY, F.R.C.S.I., Visiting Physician. Terms moderate.

PRIVATE RETREAT
FOR
THE UPPER AND MIDDLE CLASSES
OF BOTH SEXES,
MENTALLY AFFLICTED,
TUE BROOK VILLA,
NEAR LIVERPOOL.
Further information may be obtained on application to Dr. H. OWEN.
Vide page 1075, "Medical Directory," 1869.

THE MIDLAND RETREAT,
(Near Maryborough, on the Great Southern and Western Railway,)

FOR the Reception and Treatment of the Insane, and of persons suffering from a Disturbed state of the Nervous System, under the Direction of Dr. Jacob, Physician to the Maryboro' District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c. This Establishment consists of two separate and commodious residences—Anne Brook, for the reception of Ladies, Woodville for Gentlemen. Each situated on extensive grounds, with large, well-enclosed gardens. They are handsome, well-furnished country residences, where the patients enjoy the comforts and indulgences of a private house. The inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted, can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, and the North of Ireland.

CITY OF DUBLIN HOSPITAL.

DR. ARCHIBALD H. JACOB
will deliver, during the ensuing Session,
A FULL COURSE OF LECTURES
on the
DISEASES OF THE EYE AND EAR,
and the
OPERATIONS NECESSARY FOR THEIR TREATMENT.

CASE OF FISTULOUS COMMUNICATION WITH THE KIDNEY.

By Commander D. PANTALEONI, M.D.

I SEE reported in the MEDICAL PRESS AND CIRCULAR of the 16th December an interesting case of a fistulous communication with the kidney in the lumbar region. It may, perhaps, prove also interesting to your readers to see recorded another case of such a communication which I had occasion to observe two years ago.

I was called in haste to see a patient, Mr. M., an American, who was labouring under the most excruciating pains, with tenesmus, bloody and mucous evacuations, fever, vomiting, and all the symptoms of an acute and neglected dysentery. It was the sixth day of illness, and considering the extreme exhaustion of the patient and the unusual symptom of the vomiting and violence of the fever, I had very little hope of saving the patient's life. However, under my usual treatment, and excluding carefully opiates of all kind, the patient recovered.

It was then the time when I could give attention to another illness existing for several years, and of which the patient's mother had given already some hints before.

Mr. M., born of healthy parents, enjoyed as a child good health, when by accident he had the misfortune to swallow a needle or pin, which was never passed, at least as far as a watching person could state it, from the bowels. The child, however, from that time began to suffer from frequent colics, having their origin in the left side of the abdomen, and accompanied sometimes with vomiting and very often with fever and inflammation. Nothing in the constitution could explain the constant return of those attacks, which did not seem to have the slightest connection with the diet, food, or any other common cause of illness. After a while the boy seemed to grow better, and longer periods elapsed between the attacks. It was hoped that he had entirely outgrown the illness, and he could even travel for two years. However, a sudden jerk, an extraordinary exercise, a shock seemed to bring out again one of those attacks which began to be always connected with vomiting, retraction of the thigh, and other symptoms of renal irritation.

It was after some severe attacks of the kind that in the left side of the abdomen, almost in the middle of the circumference, a swelling appeared with inflammatory action, fluctuation, and all the signs of an abscess. Dr. Nélaton opened it, and a large quantity of urine and pus came out and continued to ooze without ever ceasing. Any attempt to stop the running was followed by a renal colic and incessant sufferings, till the matter opened itself in another issue, a little higher or a little lower from the previous opening. In this way a fistulous communication was established with the kidney, and to prevent the inconvenience of the constant dripping, an ingenious contrivance was invented of some metallic tubes fixed in the fistulous opening and communicating through a long india-rubber tube, with an india-rubber bag fixed to the leg of the patient, and which occasionally could be emptied of its contents by an opening conveniently closed with a stopper.

Such was the case which was presented to my observation. I collected immediately the water passed through the fistulous communication, and I found, after many days of observation and measure, that the patient passed on the average five to seven litres in the twenty-four hours of liquid through the fistula, and that the quantity of the pus represented from the fifth to the fourth of the quantity of the water, an enormous quantity, and which proved to be such a drainage to the general strength of the patient, that I thought it impossible that life could be long prolonged if I could not succeed in diminishing the amount of the losses and improve the condition of the stomach, and of the general constitution.

I tried first the local means, but the most gentle injections proved too irritating, and I was obliged to give up any further trial in this line, as a renal colic followed each attempt. The sensibility of the kidney was such a one that if the patient slept too long on the right side without turning, and remaining a quarter of an hour in this position to favour the issue of urine and pus from the fistula, an attack was threatened, and squeamishness or vomiting began. I tried to introduce a longer metallic tube, so as to be able to inspect the part with the endoscope, but their introduction proved impossible for the same reason given above. I tried then the internal astringent remedies, but none proved of great avail, as the chief consideration to me was not to disturb the stomach with unpalatable or irritating medicine, and to keep its strength for food and reparatory nutrition. With a proper diet, with exposure to the sun, and tonics, the patient had won several pounds weight. He could walk a little again, was eating and sleeping well, and seemed to go on in a stationary condition as regards the illness of the kidney. I will add here that some water was always passed by the natural canal, and which seemed chiefly to come from the right kidney. This water, when the patient took care to lie on the left side, to let the matter freely flow out from the fistula, never contained pus or albumen, but if the patient was lying on his right side a small portion of pus came through the left side. Fever was going on in the bladder, and some albumen was discovered in the water naturally passed.

I left the patient at the end of March, and I heard from him in July. He continued well, but on my return home I learnt that he had, I do not know what new attack, and he had died, in his physician's judgment, from exhaustion. No autopsy having been made of the body, I cannot but give, such as it is, this imperfect observation, and will, therefore, avoid making any further remark.

DROPSY AND ITS PATHOLOGY.

Cases under the care of Edmund P. Sharkey, M.B.

(Continued from page 525.)

N. B., female, married, æt. 60, had an attack of erysipelas in January; has been recently attacked with anasarca, affecting body and lower extremities. Prescribed a mixture containing nitre, acet. kali, tinct. scillæ, spt. eth. nitr., and spt. junip. co., with relief of symptoms.

October, 1868.—Again attacked by dropsical symptoms, which caused considerable difficulty of breathing and orthopnœa. The same remedies, with the addition of calomel and bitart. kali, were tried, but without benefit, so that anasarca made progress and the orthopnœa was more distressing.

On 27th October prescribed ext. elaterii, gr. ⅓, which acted energetically, but did not remove the urgent symptoms.

Nov. 5th.—Scarified her legs; and as the action of the ext. elaterii was severe, ext. hyoscyami, gr. ij., were added to each dose. The best results ensued; anasarca was removed; her respiration became easy, and the relief has continued to the present date (Jan. 2, 1869). She takes the elaterium occasionally, and thus holds the disease in check.

Feb. 20, 1868.—P. D., male, æt. 35, attacked lately by melænea, which had been preceded by general abdominal uneasiness for some time. He is considerably weakened; his face is pale and pasty-looking; has some fulness of abdomen, with pain in left hypochondrium. ℞ Tinct. digitalis ol. terebinth. aa., ʒij.; glycerinæ, ʒi.; aquæ ad., ℥viij. ♏ Sum. cochl. amp., ij., ter. ℞ Mass. pil. hydr., ʒss., in pils. vj., divide; quarum sum., i., o. n.

25th.—℞ Mass. pil. hydrarg., p. digitalis, p. scill. rad., gr. i. ana. ♏ Ft. pil., ter die. His urine is acid, turbid when cool, coagulable by corrosive sublimate, not by heat or nitric acid. His bowels torpid. ℞ Tinct. iodin., ʒi.; aquæ ad., ℥x. ♏ Sumat. cochl. amp. ij., ter die. ℞ Massæ pil. hydrarg., ext. hyos. a., gr. i.; massæ pil. coloc. c., gr. ij. ♏ Ft. pil., ter die.

March 2nd.—Bowels confined, and he suffers from flatulence. To take a powder of calomel and jalap and a carminative mixture; also, when state of bowels requires it, pulv. jalap. comp., ʒij.

On the 8th March the following is the report:—He complains of great oppression from fulness of abdomen, in which fluctuation is evident; constipation increases the oppression, but is relieved by the powders of pulv. jal. comp. ℞ Massæ pil. hydrarg.; pulv. scillæ a., gr. i.; digitalinæ, gr. 1-50. ♏ Ft. pil., ter die. Applicetur, empl. vesicatorium hypochondrio sinistro. ℞ Iod. kali, ʒi.; ext. sarzæ, fluid ℥j.; aquæ ad., ℥xij.; sum. cyath. vinar., i.; ter die. Under this treatment, and the use of cream of tartar drink, he gradually improved; his gums were slightly affected, and the dropsical symptoms subsided. His general health was greatly restored, and he resumed his usual avocation as a farmer.

December 10, 1868.—I met him to-day on the road looking well; but he informed me he had occasional tendency to swelled ankles at night.

The following is a case of what may be called local dropsy, and presents some rather uncommon features, which give it a degree of interest:—

September 25, 1867.—J. F., a youth of 18, attacked by what seemed at first to be severe acute rheumatism, engaging several joints at the same time; his arms, shoulders, hips, knees, being simultaneously affected with such agonizing pain, and with such an amount of fever accompanying, that I at once proposed venesection, which was declined. I then ordered calomel gr. viij., opium gr. i., to be taken at night, and in the morning mag. sulph. ʒi.

His friends became dissatisfied at what they called "the severity of the medicines," and I heard no more of him at the time. I learned, however, that the disease had proved to be general osteitis; abscesses had formed successively on nearly all the joints; and when I was called to see him again he was emaciated to an extreme degree, and presented cicatrices of abscesses which had opened from time to time; but the most extraordinary feature in his case was the strange-looking morbid specimen which his right lower extremity exhibited. If I had seen the right leg, and nothing more, I should have called it a most aggravated instance of elephant leg, merely wanting the characteristic condition of the integument. While the calf measured thirteen inches, the instep measured seventeen inches; and as I stood at the foot of the bed no toes were visible, except the first joint of the great toe; the limb was, as it were, a large serous bag, evidently enclosing a greatly enlarged bone. An incision was made into the instep, which gave issue to a great quantity of serous fluid, and gradually reduced the limb, which, however, soon resumed its former distension, and required another incision. He died exhausted on the 12th of October.

I have thus selected from my case-book several cases, no two of which probably agree in their pathology, and from which I do not pretend to draw any general conclusions. I give them solely in the hope that they may furnish perchance a practical hint to some one having an apparently similar case or cases to treat. I would merely observe that, when the combination of digitalis with mercury and squill is considered to be indicated, digitaline is the most eligible preparation, being of uniform strength; and, as I before observed, the form of granules as prepared by Messrs. Homolle and Quevenne, is, in my opinion, the most convenient.

Hospital Reports.

MERCER'S HOSPITAL.

Removal of Breast for Scirrhus.

Under the care of Mr. MacDowel.

Mr. MacDowel lately removed the right breast of a patient suffering from scirrhus. The history of the case is—that the woman, aged sixty-four, fell upon a clothes basket about two years previously, when spreading clothes to dry. The breast continued sore after the injury, and about six months ago she first experienced pain of a lancinating character, and then a hard tumour was observed a little under and to the outside of the nipple. She sought admission and came into hospital the end of January, and Mr. MacDowel removed the tumour.

It was a well-marked example of simple carcinoma; the glands in the axillæ were not engaged; the tumour was very hard, movable in the subjacent parts, and the skin was not adherent. Two elliptical incisions and a few sweeps of the knife removed all; two small vessels required ligature. The wound was dressed with phenic acid, and drawn together by adhesive plaister. Great care was observed in administering the chloroform, as the heart sounds were weak.

An egg beaten up with half a glass of brandy was administered an hour before the operation, and half a glass of brandy with four drops of prussic acid and fifteen of tinct. of opium immediately after. In his remarks to the class on the case, Mr. MacDowel urged the necessity of "selecting" cases for operation in the disease, and if possible to induce the patient to submit to treatment before infiltration of the surrounding parts, or ulceration over the tumour had taken place. He also urged *the removal of the entire gland in all cases*, and also pointed out the necessity of the extirpation of any axillary glands which were enlarged.

The statistics of cases collected by Lebert, Paget, and others, hold out but small expectation of prolongation of life; still, he could not but believe that if the operation were performed easily, and before the cancerous cachexia were developed, a much more encouraging state of things might certainly be looked for, and he referred to the case of Mary Whelan, from whom he had removed a carcinomatous breast eight months previously, and who had since enjoyed excellent health and spirits.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. Thornley Stoker, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

MEATH HOSPITAL.

Foreign Body in Bladder; Median Lithotomy performed by Mr. Porter.

John M., an active young man, aged twenty-three, a harness maker by trade, was admitted into hospital in May, 1868, suffering from a stricture, the sequence of gonorrhœa, contracted some three years previously, and in endeavouring to relieve which, by passing a gutta-percha bougie constructed by himself, he had broken the bougie, and left a portion of it behind in his bladder. This accident had happened about seven months before he presented himself to Mr. Porter, who, after his admission, commenced to dilate the urethra, which at first with difficulty allowed the passage of a No. 2 bougie, but which was gradually enlarged sufficiently to receive No. 6. He was then carefully sounded, and the foreign substance being detected, an endeavour to remove it through the urethra was made, which failed. An operation was then determined upon but refused by the patient, who insisted on leaving the hospital. He again presented himself, however, in the commencement of January of the present year, and submitted himself to treatment. His urethra remained of the same calibre as when he had left the hospital, giving passage to No. 6 bougie readily, and after some difficulty to No. 7.

The piece of bougie had now become the nucleus of a calculus, and the crushing operation not being admissible owing to the existence of the stricture, and from the fact of the foreign body being present, Mr. Porter proceeded on the 13th of January to remove it by means of the Median operation, the stone being sufficiently small to be so extracted. The man was chloroformed, the stone sounded for, detected, and removed rapidly and safely, the operation being almost bloodless. As the mass—which was very friable—was being extracted, and whilst in the wound in the perinæum, the pressure of the forceps broke it, the fragments being then taken away piece by piece, and the detritus washed out by a tepid-water injection. Mr. Porter's method of opening into the bladder is a combination of those recommended by Allarton and Sir Henry Thompson, the former surgeon dividing all the parts by transfixion, and the latter by dissection, whilst Mr. Porter prefers dissecting through the skin and superficial fascia, and transfixing the remaining structures.

The fragments of the stone, which was phosphatic, when washed and dried, weighed 140 grs., and in the largest of them was found imbedded the piece of gutta-percha, in length about three-quarters of an inch, and in diameter about one-eighth of an inch. On this fragment a well marked facet existed, but only one stone had been detected, and the other pieces showed no trace of a corresponding surface.

After the operation the patient was placed in bed, with his legs drawn well together, and was given a suppository containing one-quarter grain of morphia. He enjoyed a good night's rest, a luxury he had not known for more than a year. He made a rapid recovery, no medicine being necessary, save an occasional dose of Battley, and no topical application excepting a strip of adhesive plaister to the wound.

◆

REPORT OF CLINICAL LECTURES

DELIVERED AT

ST. GEORGE'S HOSPITAL.

By Mr. Henry Lee.

CASES OF MORTIFICATION, AND OTHER SECONDARY AFFECTIONS CONNECTED WITH DISEASE OF THE ARTERIES.

(Continued from the Medical Press, *Jan.* 27.*)*

Case III.—J. P., æt. 53, after a long previous indisposition, was suddenly attacked with violent pain in the back and loins. He apparently fainted from the effects of the pain, and did not recover.

Upon a *post-mortem* examination, the body was found loaded with fat. The omentum alone weighed more than a pound. The anterior and posterior edges of the right lobe of the liver both presented a discoloured patch. These patches were black in the centre, and gradually assumed a lighter shade towards the circumference, where the tissue of the liver appeared as if it had been dusted with gunpowder. The pancreas was almost entirely disorganized; a small portion, about the size of a Windsor bean, only remained connected with the duct on the right side. This retained its natural structure.

The remainder, of a saffron colour, presented a gelatinous mass, in which the duct terminated at about what would have been the junction of the middle third of the gland with its head. The inner coat of the gall-bladder was firm and rigid; the outer coat was very flaccid, and the two were separated by a gelatinous fluid. The capsules of the spleen and left kidney were filled with matter of the colour and consistence of black-currant jelly. The left kidney presented two cysts, containing together from ten to twelve ounces of fluid. The diaphragm, where it lay in contact with the spleen, was softened so as to be lacerated with very slight force.

The walls of the left ventricle of the heart were twice their natural thickness, and softened so as to be easily broken down by the finger. There was a small rim of bone between the right auricle and ventricle. The aorta-valves were not ossified, but on passing the finger into the aorta from the heart, a plate of bone, loosely attached, was separated. This led to a further examination of the aorta, which presented from the termination of the arch to the bifurcation a complete column of bone. Between these points spicula of bone radiated from the circumference towards the centre of the vessel. The pancreas and gall-bladder in this case were affected in a very different way to the liver, spleen, and kidney. They presented no black deposit, and appeared simply softened.

Case IV.—E. S., a young man, came under my care on the 2nd of January, 1868. On the outside of the legs corresponding to the distribution of the branches of the fibular artery were several irregular sores, covered by a gray phagedænic surface, and discharging a thin serous fluid. Portions of the neighbouring parts were enlarged with solid œdema. The edges of the ulcers were undermined and livid. In some parts obscure fluctuations could be felt under portions of skin very little altered in appearance. In other parts, where no fluctuation could be detected, the parts felt "boggy." The affection had at that time lasted nine months, and he had tried a great variety of remedies.

This patient remained under my care during the years 1866 and 1867; a variety of treatment was adopted during that period. The only remedy which appeared to produce any decided benefit was the local calomel-bath. This he commenced when I first saw him, and resumed on several subsequent occasions.

It was not, however, until the end of 1867 that the leg appeared permanently cured. On the 28th of February my patient wrote to me stating that his leg "appeared to have recovered its natural power, and felt in walking almost as strong as ever."

Case V.—Ellen S., æt. 32, was admitted under my care into St. George's Hospital on the 3rd March, 1868. She was married, and had four healthy children, the youngest five months old. On the outside of the left leg were a number of small round ulcers, presenting phagedænic surfaces, with livid undermined edges. The affection commenced two years previously, with a small swelling on the lower and outer part of the popliteal space. This increased gradually and slowly, and attained its full size a year ago, after which it subsided. The present ulcers had been in existence twelve months, and had become at times sufficiently painful to prevent her walking; there was no swelling of the foot.

This patient's history was carefully examined into, and no cause for the ulcerations could be found beyond the swelling in the popliteal space above mentioned.

The ulcers rapidly improved under local calomel fumigation repeated twice daily; and the patient left the hospital on the 1st of April.

Case VI.—Mrs. L., æt. 44, came under my care on the 12th January, 1868. She had had one miscarriage soon after her marriage nineteen years ago; and had not been regular for two years. When first seen, the leg and foot were swollen to about double their natural circumference. The swelling was caused by solid œdema. Ten or twelve ulcers in different stages of development existed down the outside of the left leg. Three ulcers in this case existed also upon the inside of the leg. The knee was contracted. Extensive induration occupied the popliteal space. She had been unable to walk for several weeks, and was apprehensive that she would not regain the use of her leg. The affection had commenced nine months previously; a small red lump then appeared over the head of the fibula. This was soon followed by swelling in the popliteal space and over the ankle. Small circumscribed oval tumours then formed in different parts. These in process of time became softened, and discharged a thick pus of the consistence and appearance of softened cream-cheese.

The treatment consisted of local calomel fumigation morning and evening, the application during the day of a lotion of sulphate of copper, and a carefully-applied bandage. Iodide of iron was given internally. Fresh abscesses, containing the same cheesy fluid, were opened on the 18th and 28th of February. The ulcers now all began to heal.

At the latter end of March the leg was reduced to about its natural size. The ulcers had all nearly healed, and the patient was able to walk.

September 3, 1868.—This patient called to show herself. The leg was now nearly straight. She could walk for half an hour. The ulcers all remained apparently permanently healed, with the exception of one spot the size of a pin, which still secreted some pus.

Case VII.—During the latter part of the year 1866 and in 1867, I saw, in consultation with Dr. Quain, a lady who for several months had had a number of small circular ulcers on her leg. These, as in the former cases, commenced with indurations in the cellular membrane. The skin covering them after a time became implicated. It would gradually become thin and give way; but previously to this, and even before the skin became discoloured, fluctuation could sometimes be detected in the subjacent parts.

In Case III. the diseased appearances followed exclusively the distribution of the branches of the cœliac axis and of the renal arteries. The theory of a *materies morbi* being conveyed through the blood could alone account for the simultaneous appearance of disease in such different parts. The case occurred many years ago, and the examination was conducted in a private house. No specimen could be preserved, or further details of the case would be given. In Cases IV. and V. the affection was confined to the parts supplied by the fibular artery, and in Cases VI. and VII. to parts supplied by the tibial and fibular arteries.

It is unnecessary to dwell upon the analogy between the process of softening in connection with diseases of the arteries of other organs, and the affections of the brain from the same cause, so ably pointed out by Dr. Kirkes. In both cases, however, Mr. Lee considers the changes observed to depend rather upon an alteration in the quality than the quantity of blood supplied to the parts. In an organ in which the anastomoses of vessels are so free as in the brain, it could hardly happen, while the quality of the blood remained unchanged, that the supply could be arrested through any one large vessel so as to affect exclusively any one part of its structure.

The disease, of which the above-mentioned cases afford illustrations, is a strictly local affection, confined generally to one limb, and attended with very little, if any, constitutional disturbance. It commences with small circumscribed swellings in the cellular membrane. The skin over these remains for a time of its natural colour. It becomes red, and subsequently livid. It then ulcerates, and some thick fluid that has formed in the tumours is discharged; the skin is now left undermined, with irregular livid edges. The patient may go about his occupation as usual, and appears to suffer very little in his general health; and were it not for the pain which he sometimes experiences, would be little inconvenienced by his malady. These abscesses are of very slow development; and as some heal, others will make their appearance; and thus the disease may continue for some years.

These abscesses will form in considerable numbers; each being separate and distinct from the others. When healed they may present the outline of a bunch of raisins flattened; the circumference of each separate patch encroaching more or less on its neighbours. They are generally accompanied with some swelling of the limb; and in one case this swelling attained a very considerable size. From the local nature of these tumours, from their chronic character, from the number of places simultaneously affected, and from their tendency to suppurate, Mr. Lee calls them "CHRONIC LOCAL MULTIPLE ABSCESSES."

In Case IV. there was a history of specific constitutional disease. In Cases V. and VI. there was no such history.

In Case VI. the ulcers existed on the inside as well as on the outside of the limb, and the swelling affected the foot as well as the leg. It is possible, therefore, that the tibial and fibular arteries both had to do with the production of the disease; and that the fibular artery alone was implicated in Cases III. and IV., where the swelling was confined to the leg.

In Case VII. the disease appears to have been communicated. The history is, however, not satisfactory, and there was no opportunity of carrying out any systematic plan of treatment. The case was most obstinate, and a number of medical men were consulted, but without benefit. The point of interest in the case is that the husband had what appeared from description to have been a similar affection some time before. The disease in him was also most obstinate, and the ulceration very extensive. He described a place in his leg that he could "put his hand into;" but this appears to have given him little inconvenience, and not to have interfered with his general health, as he hunted with it for a whole season. After his leg got well, which it seems to have done without any particular treatment, the scalp became affected. This affection, which came under Mr. Lee's care, was also most obstinate. Several small circumscribed abscesses, surrounded by induration, were open at the same time, discharging a large quantity of pus. These abscesses in places extended under portions of skin very little altered in appearance. This condition continued during many months, the patient's general health being unaffected.

The conclusions to be drawn from the cases and Mr. Lee's clinical remarks, which we have thus fully reported, may be summed up as follows:—The morbid products of diseases of the arteries (whether originating in them or communicated to them from other parts) may mingle with the blood. These morbid matters consist chiefly of the results of fatty degeneration, and of fibrin-like matter formed in the vessels. Such products, mixed perhaps with the *débris* of the arterial tissues, may either mechanically, or by inducing coagulation of, or deposit of fibrin from the blood, impede the circulation. The tendency to this deposition of fibrin, and the process of cell-development which may commence in such deposits in one of the larger arteries, may be continued to a much greater extent in the capillaries. The actions in these are essentially of the same nature as in the larger vessels, although the material in which they occur may have been transferred from its original site. The principal secondary effects attributed by Mr. Lee to the causes above mentioned are (1) gangrene, (2) softening, (3) solid œdema, and (4) chronic local multiple abscesses.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

February 1, 1869.

Dr. B. W. **Richardson**, F.R.S., President, in the Chair.

Mr. **Spencer Watson** narrated a case of

SLOUGHING POLYPUS OF THE ANTRUM,

and exhibited a specimen which had been extruded by an act of vomiting.

Dr. **Bateman**, of Norwich, read a paper

ON APHASIA.

The author confined his remarks to one point—the localisation of the faculty of speech. After reviewing the various terms (anandia, alalia, apemia, aphasia) applied to lesion of this faculty, the author stated his preference for the last, and connoted by it loss of the power of speech from whatever cause.

Many situations in the encephalon have been assigned to the faculty. Besides other portions indicated by other observers, the following were the most important:—

1. Schroeder van der Kolk placed it in the *corpora olivaria*, and the view was supported by Jaccond. The answer to this theory, according to lessons derived from seventy-two cases collated by the author, was, that in *three* only was there lesion of this portion; and examination of Schroeder van der Kolk's cases disclosed other important lesions besides that to which he attributed a causative relation.

2. Bouilland assigned it to the anterior lobes of the cerebrum. Cases seemed to give this theory a greater confirmation than the former; but it was opposed by the fact of there having been instances of the most complete destruction of both anterior lobes without loss of speech. Moreover, Velpeau brought forward the case of an idiot who could articulate although there was *congenital* absence of the frontal lobes.

3. Dax assigned the faculty to the left hemisphere; but

4. Broca arrived at the *ne plus ultra* of pathological topography by placing it in the posterior portion of the third left frontal convolution. The very case on which Broca built his theory has been assailed as to the facts concerning it by Béhier, under whose care the patient was before he came under the hands of Broca. Many other observations showed that this exclusive theory could not hold.

Comparative anatomy showed the probability of there being a near relation between speech and the grey sheath of the convolutions. Moreover, injury to the convolutions in dogs impaired the barking powers of the animals.

In illustration of the relation between speech and other intellectual functions, the author narrated a very interesting case in which, though there was no power of voluntary speech, there was an exaggerative faculty of mimicry.

In conclusion, the author doubted the existence of any *centre* of speech. Aphasia may depend upon a want of co-ordinate action, as well as upon lesions of the nervous system attended with no appreciable signs.

After some observations by Dr. **Rogers**,

Dr. **Hughlings Jackson** lucidly explained his views upon the questions. At first, observing aphasia, hemiplegia, and valvular disease of the heart to co-exist, he was inclined to the belief that in plugging of the cerebral arteries there was a *vera causa* of the symptoms. Soon, however, he found that clot as well as embolism could be a cause. His views in many ways agreed with the author's. Aphasia could be none other than a term of relation—it is a most *inconstant* quantity. He believed that the left side of the brain was, in most cases, the leading side, the right the automatic.

Dr. **Webster** believed that the situation of the centres of voice was in the anterior lobes. The tendency to use the right limbs required for its explanation no assumption of the diverse endowment of the two hemispheres. It is merely a question of education.

Mr. **Dunn** divided aphasia into (1) structural, (2) functional. He believed that the intellectual centre of speech was in the anterior lobes, the motor centres thereof in the corpora striata.

Dr. **Semple** considered the subject too difficult for dogma. There is a disturbance of equilibrium in these cases such as finds its parallel in the disturbance of electrical phenomena by external conditions.

After some observations by Dr. **Thorne** and Mr. **Hill**,

Dr. **Marcet** said he believed aphasia to be either organic or functional. It could occur without disease of the brain. There were cases of *temporary* aphasia, of which he cited examples.

Mr. **Rogers Harrison** believed that speech is not an intellectual function "pure and simple," but that it is the result of education.

Dr. **Routh** suggested the investigation of the pathology of the opposite error—loquacity—hyperphasia, as Dr. Bateman termed it. Chemical examination of the urine might throw some light on this obscure subject.

Mr. **Streeter** pointed out some anatomical errors. He objected that the so-called "fissure of Rolando" is no fissure at all.

The **President**, narrating some interesting experiments on congelation of the brain of pigeons, observed that pathological examination failed to detect any alteration of a brain whose function was impaired by cold. In reference to the subject of aphasia, as well as to other cerebral lesions, the lesson was taught that lesions presenting the most pronounced objective symptoms could exist without any sign detected after death.

The author, after having been congratulated upon an able paper, made a succinct reply.

DUBLIN PATHOLOGICAL SOCIETY.

December 19, 1868.

ANEURISM OF ABDOMINAL AORTA.

The morbid specimen exhibited a remarkable example of aneurism of the abdominal aorta, which occurred in a patient that was under Mr. Stokes's care in the Meath Hospital for some months at the close of the year 1867 and beginning of 1868. The patient was a man æt. forty-two, by occupation a cattle-drover. He had always been temperate, but was occasionally exposed to much hardship. Up to four years previous to his admission into hospital he was in perfect health. He never had illness of any kind, except fever when a boy. It was not rheumatic. He first noticed pain in the left side. Three months later it settled down in the back and became of a boring character, the pain was paroxysmal and preceded by numbness in the left arm. The paroxysms occurred about twice a day; sometimes at night also. His bowels were generally confined. On examining the abdomen a large abdominal tumour was found pulsating forcibly, and a distinct fremitus was felt on applying the hand over it. A loud rough murmur was also distinctly heard on applying the stethoscope over the tumour. There was one very remarkable and unusual feature in this case, namely, the extreme irritability and violent action of the arteries on the distal side of the tumour. The femoral and iliac arteries were always pulsating violently throughout, until the man's death. Mr. Stokes had never seen any patient suffer greater agony than this man endured. At first a paroxysm occurred about twice a day, but afterwards they became not only more frequent but also more violent. The only treatment that could be tried in this case was palliative—viz., the exhibition of opium, and he never met any case in which the subcutaneous injection of morphia produced a more beneficial effect. At first, when a paroxysm came on, a single injection of morphia, 10-15 minims of the liq. morphiæ was sufficient, but as they became more frequent and increased in intensity a much larger quantity was found necessary, and Mr. Kerans, who had charge of the case, drew his attention to the fact that shortly before the patient's death, a ten-grain solution of morphia was used, and an amount equal to one grain of morphia was injected two or three times in the day. This continued for several months, but at last he began to sink, when another remarkable symptom appeared, namely, dropsy; and the man died not from any rupture of the sac, or effusion of blood into the abdomen, but from exhaustion, pain, and pleuritic and pericardial effusions, which took place shortly before his death.

Autopsy.—There was enormous hypertrophy and dilatation of the left ventricle. The aortic valves were also insufficient, they were not capable of holding water, and were also much thickened, the other cavities of the heart were also dilated; there was great dilatation of the arch of the aorta and extensive etheromatous deposit all over it, which continued throughout its whole course. The lungs were healthy, but the pleura contained about thirty or forty ounces of fluid, there was also about six ounces of fluid in the abdomen.

There was a large aneurism low down in the aorta, about the size of a small cocoa-nut, which sprang from the posterior wall of the artery, partly eroding the third, fourth, and fifth lumbar vertebræ. The remarkable circumstances in connection with this case were its complications with cardiac and aortic disease, the situation of the aneurism being very low down; the peculiar throbbing of the arteries on the distal side of the tumour which appeared to be analogous to the violent arterial excitement in those cases of pericarditis that were associated with violent action of the carotids would lead them to suppose that there was some possible connection between the aneurismal formation and the inflammatory process. Mr. Stokes did not know of any similar case on record in which ascites occurred. This circumstance caused additional difficulty in establishing a diagnosis between this disease and cancer of the abdomen, which was generally associated with partial ascites; taking this remarkable complication of symptoms into consideration, this case in his opinion was one of extreme pathological and clinical interest.

Dr. Barton, at the request of his colleague Dr. Richardson, under whose care the patient was, exhibited a specimen of a diseased femur.

From the nature of the sequestrum, its peculiar condition, and there being extensive accompanying ostitis with corresponding constitutional disturbance, the amputation of the limb had become necessary. The disease was the result of an injury received two years before the present time; the man was thirty-six years of age, a cooper by trade, and received a severe crush between two heavy barrels; he was able, however, to walk a considerable distance next day. The day after he was attacked with acute symptoms of pain in the limb, which necessitated his remaining in bed, where he continued for some weeks.

An abscess formed, and was opened, and a sinus was left remaining at the upper aspect of the thigh; this sinus discharged a continual but not very large amount of pus, and during the following year a small piece of bone made its escape. In Sept. 1867, the man was admitted to hospital for the first time, and a probe passed down into the sinus detected dead bone. There was another opening in the posterior portion of the limb, but no dead bone could be found. After sometime he returned to his work. A year afterwards he was again admitted to hospital, when from excessive discharge, increasing pain, and lameness, he was obliged to give up business. This was in the month of Sept. 1868. A careful examination of the diseased bone was then made, at the bottom of the upper fistula some soft bone was felt as in ordinary necrosis, pressure over the femur caused a gush of healthy pus from the opening. He never saw any man labouring under necrosed bone suffer so much as this man did, so much so that to make a thorough examination without chloroform was impossible; the cause of which was explained subsequently The probe when passed into the lower opening came into contact with living substance, in the upper one, it came down on dead bone. The constitutional symptoms demanded some interference; night-sweats commenced, the patient's health began to deteriorate from the copious purulent discharge. Mr. Richardson feared that his health would run down and pyæmic symptoms come on, and therefore determined upon an exploratory operation to remove the sequestrum, and if that could not be done to remove the limb by amputation. The attempt was made to remove the sequestrum, but it was found impossible to do so, and the operation of amputation was completed.

Upon examination of the limb, a large sequestrum was found lying obliquely through the shaft of the femur, about six inches in length, movable indeed, but not upwards, and the lower part of it lay exactly behind the popliteal artery, which impinged upon its very end. The femoral artery was immediately below the upper opening. Not only was there this difficulty as regards the removal of the sequestrum, but they found a condition of chronic ostitis at the lower end. Dr. Barton exhibited a drawing showing the condition of the bone at the time of removal. It had a deep dull red colour, extending round the cancerous structure of the bone, which was cheesy and soft.

The specimen was interesting, not only from the difficulties which resulted from the peculiar position of the sequestrum, but also from the existence of chronic ostitis, which, while it accounted for the extreme pain which the patient suffered, rendered any operation short of amputation useless.

JANUARY 16, 1869.

Dr. Eames said the morbid specimen which he now exhibited was taken from the body of a boy who was admitted to Mercer's Hospital on the evening of the 24th December. His mother was in service, and he had been placed at nurse in the Dublin Mountains, and seemed to have been neglected. He had been ailing for a long time before his admission to hospital. When Dr. Eames saw him for the first time, on Christmas morning, he was complaining of great pain in the knee and ankle-joints, which were much swollen and reddened; he evidently suffered much pain when moved. The skin was covered with perspiration, which had the peculiar smell of rheumatism. On examining the heart, a loud to-and-fro sound was heard over its base, and on percussing it there was no increase in the area of dulness. On the next morning the peculiar sound was increased, but there was no increase in the area of dulness; and so he went on for two or three mornings, gradually getting worse. The pulse was 150.

About the 28th signs of effusion began to take place. The friction sound, which had previously been so loud that it could be heard by the ear an inch and a half from the chest, became lessened, and effusion took place into the pericardium. At this time he discovered that the boy had a very large bed-sore over the sacrum, which he ordered to be dressed.

The patient became worse; the effusion became very great, so that, as he lay on the left side, the dulness reached to the right nipple and to the lower border of the second rib. Having been obliged to go to the country, Dr. Mason kindly took charge of the case for him; and when he returned, on the 10th January, he found that the patient had an erysipelatous patch over the left eyebrow, which exhibited a considerable amount of tumidity. The boy, whose condition had, in fact, been very bad when he came into the hospital, began to decline rapidly, and finally died.

Autopsy fourteen hours after death.—On raising the sternum and costal cartilages, the pericardium was seen bulging forwards, its surface covered with a network of injected vessels. The sac was much distended, reaching upwards to the upper border of the second rib; on the right side beyond the right nipple; on the left it had pushed the lung upwards and backwards, and seemed to occupy the entire left side of the thorax. The diaphragm was horizontal, or even slightly convex downwards. The pericardium was tapped, and nine fluid ounces of straw-coloured fluid drawn off; about three ounces more could not at the time be drawn off, so that the liquid effusion reached twelve ounces.

On opening the abdomen pus was observed in the right iliac fossa. On raising the intestines this was found to proceed from a slit in the iliac fascia. The idea occurred to me that possibly there might be some connection between the bed-sore and this collection of purulent matter. The body being rolled over, the sore was found to follow a sinuous course to the sacro-iliac synchondrosis. A probe was now introduced, and readily passed between the sacrum and ilium. The cartilage was completely eroded, as was also the periosteum of the ilium in many places. Dr. E. exhibited the parts, pointing out the erosion of the cartilage. Pus occupied the entire iliac fossa, and following the course of the conjoined tendons appeared at the lesser trochanter. The left knee-joint was full of pus; the other joints free from pus. The liver, spleen, and lungs were carefully examined, but no trace of purulent deposit found in them. On slitting up the pericardium both the visceral and parietal surfaces were found intensely injected. Behind and above the apex the two surfaces were adherent over a space about the size of a two-shilling piece. There was a vast quantity of lymph laying upon the surface of the heart. About the great vessels the depth of this layer equalled fully half an inch. The endocardium and valves were very vascular, but free from lymphy deposits. On a very careful examination of the heart there was found a deposit of pus in the posterior wall of the left ventricle, just below the origin of the aorta. This deposit was about the size of a grain of No. 2 shot, and was within the muscular substance of the wall. Examined under the microscope it presented all the characters of pus. The fluid drawn off from the pericardium was also examined under the microscope, but no pus globules could be detected.

ODONTOLOGICAL SOCIETY.

At the usual monthly meeting, held on the 1st inst., J. Barrett, Esq., President, in the chair,

Mr. Sewill, M.R.C.S., read a paper—

ON THE COMPARATIVE VALUE OF THE MATERIALS USED IN TAKING IMPRESSIONS OF THE MOUTH.

Mr. Sewill's object was not so much to lay down any positive rules as to give his own experience in the hopes of raising a discussion.

The **Chairman** and other gentlemen gave their respective views as to the use of gutta percha, stense composition, plaster of Paris, and wax.

Mr. **Sewill**, in replying, rejoiced that the advocates of wax were so silent, while the Chairman equally regretted the circumstance, and considered it as by no means a conclusive argument against that material. No positive conclusion was arrived at as to which was the best material in all cases. The general opinion seemed to be that much depended on the nature of each individual case.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

A quarterly meeting of this Association was held at the Freemasons' Tavern, Great Queen Street, on Friday, the 29th ultimo.

Dr. **Rogers**, the President, took the chair, and delivered an address of considerable length, the object of which was to place before the meeting, first, the position of the Poor-law medical officer in this country at the present time; secondly, to point out the extent of his grievances, and the causes to which he believed them to be due; thirdly, to show, by the letters received from many eminent sources, that the cause had secured the attention and enlisted the sympathy of intelligent people; fourthly, to give the figures necessary for the elucidation of the question, and a comparison of two systems in operation together in an empire; and to show from that comparison, that the principle of increased medical facilities was founded, not only on sound theory, but borne out by absolute and he believed incontestable experience.

The Council presented their quarterly report, in which they announced the accession of many new members, and detailed their labours in obtaining Parliamentary support. They stated that promises of support had been received from 89 Members of the new House of Commons, and that a mutual interchange of good offices had been agreed upon with the Irish Medical Associations, who were very desirous of obtaining superannuation allowances.

Dr. **Rogers** moved the adoption of the report.

Dr. **Fowler** (East London Union) seconded the same, and in so doing expressed his concurrence in the President's opinion, that liberal medical treatment of the sick poor was the ratepayer's best economy. If this had been attended to before, Gathorne Hardy's Act would not have been needed. The figures under "medical relief" in the Poor-law return were very fallacious and unjust to the medical officers. The public fancied that all, or at least the greater part of this amount went into their pockets, whereas under this head were set down not only medical officers' salaries, but also drugs, appliances, wine and spirits, subscriptions to hospitals and institutions, in fact, anything spent over the sick.

Dr. **Dixon** (Bermondsey) moved the first resolution, that the salaries of medical officers had been fixed by the guardians without regard to any uniform standard of remuneration, and that for the most part they were inadequate for the onerous duties they had to perform. In support of the resolution, Dr. Dixon entered into statistics to show, that, when the cost by medicine had been deducted, the medical officer's average pay in the metropolis was 6½d. per case; and in the country districts, 1s. 9½d. To show the utter want of uniformity, some were receiving nearly 3s. per case, while others received only 3d. Their pay was worse, he contended, than that of skilled mechanics. Medical officers in the navy and even in gaols were far more liberally treated, and better considered.

Dr. **Welch** seconded the resolution. He had been 14 years medical officer in Bethnal Green. His work had very largely increased. In 1865, the number of cases was 1,213, and they had risen in 1868, to 2,198. During the prevalence of an epidemic the guardians retained the services of a professional man, and paid him for a very limited period £106 4s. He had made a calculation, based on this gentleman's rate of payment, and he found that according to the same scale he (Dr. Welch) was entitled to £1,600 a-year, and yet the guardians demurred to raising his salary of £120 a-year.

Mr. **Hogg**, a member of the St. Giles's Board of Works, moved that the President's address should be printed and extensively circulated, in order that the facts might be put well before the public.

Dr. **Firth** (of Rotherhithe) seconded the motion.

Dr. **Goddard** moved the third resolution, which concerned permanency of appointment. He maintained that to make a medical officer free and independent in the exercise of his duties, and not merely timeserving, he ought to be permanently appointed. He considered this quite as essential in a medical officership as in a chaplaincy.

Dr. **Thomas** seconded the motion.

Mr. **Benson Baker** moved the fourth resolution, that medical officers were justly entitled to superannuation, in common with the members of the Civil Service. Medical officers had no half holiday, no vacation, their occupation was uninterrupted. Therefore they were as much entitled, he considered, to superannuation allowance, if not more so, as any other class of public servants.

Dr. **Smythe** seconded the resolution.

The fifth resolution was moved by Dr. **Smythe** and seconded by Dr. **Claremont**, that a petition embodying those resolutions should be presented to the House of Commons. It was likewise resolved to send a copy of the Council's report and of the proceedings of the meeting to the Right Hon. the President of the Poor-law Board.

The meeting closed with a vote of thanks to the President and the Council.

SURGICAL SOCIETY OF IRELAND.

We are compelled, from pressure on our columns, to hold over the report of the above Society till our next issue.

Correspondence.

THE SANITARY CONDITION OF NICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the autumn of last year (1868), several letters appeared in the London *Times* respecting the sanitary condition of Nice. The statements they contained have never, so far as I have seen, been contradicted; nor, indeed, would it have been possible for anyone having regard to truth to have done so; but as another London paper, having a very large circulation, has recently been publishing descriptions of this place, in which everything is painted *couleur de rose*, and one of which winds up with the astounding assertion that English families will find themselves able to live here very economically during the winter, I think you would be doing good service to our countrymen if you would allow me to give them the results of my experience. Retired from the active practice of the profession, and wishing only "to husband out life's taper to the close," I have spent a large portion of the last four winters in this town, and am therefore, perhaps, tolerably capable of forming an opinion as to the climate and its average effects upon the constitutions both of the healthy and diseased. With regard to the sanitary condition of the town, it is impossible to deny that the abominations complained of in the *Times* continue in full and unabated force, as far as the drainage is concerned. To those of your readers who are not acquainted with Nice, it may be sufficient to say, that the town is traversed by a mountain torrent, and that into this the principal portion of the drainage of the town is brought down; the remainder is brought by several drains which open on to the beach near to the mouth of the river and close to the best part of the town, and the most fashionable hotels; here it is simply allowed to filter out on to the shingle and to fester in the sun; and inasmuch as the so-called river scarcely ever presents any appearance but that of a few isolated pools of water, I leave your readers to imagine what must be the effect of this ever-increasing mass of fœtid matter. It is true that during the last year a portion of the river opposite the Grand Hotel has been arched over, and a public garden is now in course of construction in it, so that at this particular spot it is possible to escape from the *mauvaises odeurs* which almost everywhere else assail you in walking by the river. The only other sanitary work that I am aware of has been the construction of an intercepting sewer in the upper part of the river, which collects the contents of a number of small drains, and discharges their united contents into the river by the old bridge. This, however, as far as the portion of town inhabited by the visitors is concerned, only intensifies and concentrates the mischief.

The effect of this state of things, as to the nature and amount of disease which it is capable of producing, evidently is likely to vary very much according to the condition of the atmosphere and weather—for instance, last year, when there was almost a total absence of rain during the entire winter, the air laden with dust and charged with the noisome exhalations of the river, became excessively irritating to the mucous membranes of the throat and nose, and a peculiarly distressing catarrh and every form of sore throat became almost universally prevalent, and sudden and violent attacks of diarrhœa were by no means uncommon; in some instances these complaints were accompanied by, or followed by, a peculiar form of imperfectly marked intermittent fever of a very intractable character, continuing in one case for upwards of two months, and only being finally got rid of by the patient removing to Pau. I remarked also the same form of fever in the winter preceding—1866-7. *This* year, owing to the circumstance of a very large and unusual amount of rain, it has been much more healthy; nevertheless, in a milder form, the same class of diseases has to some extent been developed.

With regard to the general effect of the climate irrespective of disease manifestly arising from defective sanitary arrangements, I must confess that, had it not been that other places such as Montpellier, for instance, have formerly been highly praised as sanitaria, which have now fallen altogether into discredit, I should have been utterly at a loss to understand how this could ever have acquired a reputation as a climate suitable for invalids—certainly for the diseases for which it has been usually recommended I can scarcely imagine one so little likely to produce beneficial results—subject to rapid and violent fluctuations of temperature—an amount of carefulness, which it would be vain to expect from the ordinary run of invalids, is absolutely necessary to prevent the most mischievous effects. Exposed not unfrequently to the scorching sun on the one side, and a bitterly cold wind on the other,—enveloped occasionally in a cloud of dust raised by the Mistral, not only is it impossible for the patient suffering from lung disease or bronchitis to derive any benefit from such an atmosphere, but the more hardy can scarcely escape from it with impunity; indeed, I have known several cases of visitors who have arrived here perfectly well being seized with catarrh immediately on their arrival, which has never left them so long as they remained here.

In far advanced cases of consumption I am satisfied that the lung breaks down more rapidly than in England, while the unhappy patient, cut off from home comforts and home nourishment, finds but a poor compensation in the slightly better climate and temperature, and sinks quickly and painfully into the grave. As might naturally be supposed in such a climate, rheumatic and neuralgic affections not only do not derive benefit, but frequently seem aggravated, by a residence in Nice—certainly they are among the ailments most commonly complained of by visitors here who have even been previously free from them. In some cases of scrofula, of dyspepsia, and hypochondriasis, the climate of Nice by the great number of dry and sunny days, and the opportunity it affords for out-of-door exercise to those strong enough to take it, is likely to be beneficial; and, to the latter class of patients, the distractions so freely provided may assist in taking off from himself much of his gloomy thoughts, but to the really delicate invalid the ceaseless round of balls and concerts becomes merely a danger and a snare. Lastly, as regards the cost of living here—too frequently a matter of very great importance to those in search of a less inclement climate than their own—the statement that families may live here cheaply, is simply untrue. The prices of everything at Nice have rapidly increased from what they were, even five years ago, and the hotels are certainly now as expensive as the best houses in Paris, while the food and accommodation provided are decidedly inferior. Those who have visited the Louvre or the Grand in Paris will know what this signifies.

That much might be done to improve the healthiness of the town by the adoption of a system of drainage sufficiently comprehensive to collect into one channel the whole sewage of the city and carry it out to a distance, instead of allowing it as at present to pollute the atmosphere of the most frequented and fashionable quarter, I do not deny; but until compelled (possibly by some epidemic visitation, which, by scaring away their visitors *en masse*, shall threaten them with absolute ruin), I fear that the good people of Nice are far too parsimonious to undertake so costly a work. Until, however, by some means this is accomplished, it is absolutely certain that every year Nice must inevitably become less and less desirable as a refuge for the invalid, and more and more dangerous as a home for the healthy. I am, Sir, &c.,

John Hawkins.

PROFESSIONAL EDUCATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The whole profession is indebted to you for the admirable series of articles on this subject now publishing in your columns. I do not agree with all the views expressed in those articles, but I am convinced that they constitute one of the most able expositions of the whole subject that has yet appeared. It must require courage on the part of the editor to give up his columns for such an exhaustive series on a subject we might have thought worn threadbare, and which many readers—disgusted with the twaddle that has been forced upon them by jejune contributors to other papers—might be likely to pass over the moment they caught sight of the title.

I congratulate you, Sir, on that courage, and the profession on possessing an organ presided over by one who has placed your journal in the position it has lately won for itself. However "flat, stale, and unprofitable" certain subjects may become by force of always being written and talked about, it must be certain that the profession must retain a vivid interest in points affecting its own composition, the position of its members, the rules by which it is governed, and the mode in which it is reinforced. Continue, Sir, to treat such subjects in the thorough and explicit manner you have introduced into professional journalism. Encourage writers who have mastered the questions they treat to afford the "strong meat" that some of us are able to digest, and for the sake of which we can put up with the appearance of much "milk" for weaker brethren.

I do not propose at present to enter on a statement of my differences with the opinions expounded in those articles; firstly, because it will be better to wait till they are concluded; secondly, because it would be unjust to force upon such a writer's attention opposite views while he is engaged in so admirably marshalling his own. On a future occasion I shall perhaps be glad to set forth my own notions.

I am, your obedient servant,
A Medical Teacher.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—By desire of the President of the Society for Relief of Widows and Orphans of Medical Men, I beg to forward you the following particulars, thinking the information may be acceptable to the members of the profession:—

During the last year, the total amount distributed in relief was £2,504 10s., the number of recipients being fifty-four widows and twenty-six children.

Additional relief was granted to two widows and two children from the Copeland Fund. This fund the directors were enabled, through the great liberality of the late Thos. Copeland, Esq., to form for giving additional assistance to widows and orphans already in receipt of ordinary relief, under special circumstances of unusual distress from great bodily or mental infirmity.

The Society, although at present able to meet the demands made upon its funds, cannot continue to do so unless well supported by the richer members of the profession. The number of applicants is yearly increasing, and likely to do so, as a reference to the list of members will clearly prove.

Trusting you will kindly accord a prominent notice in your journal of the foregoing statement,

I am, Sir,
Your obedient servant,
Jos. B. Blackett, Secretary.
53 Berners street, Feb. 4, 1869.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I see by your issue of to-day that you have altered the date of my letter on "Poor-law Reform" from *November 6th*, 1868, to *January 6th*, 1869. Now this materially affects some portions of my letter, and requires some explanation, as, since I wrote that letter, Dr. Lemon has either been called upon by the Poor-law Board to resign a portion of the districts he held, or else he has resigned a small portion of his own free will; this small portion has been advertised in one of our local papers, and I had a circular from the Clerk to the Board of Guardians of the Clun Union, requesting my attendance on the day of election, January 13th last. I append my answer thereto:—

"*Bishop's Castle, Jan.* 12, 1869.

"Gentlemen,—Perhaps your clerk will explain to you why a circular was sent me yesterday requesting my attendance at your Board-Room next Friday, relative to the appointment of a Medical Officer for Lydbury, North District, of the Clun Union.

"I have no objection to attend the poor of that district up to 25th March next, as "private patients," or for £15; but to take such a small portion of the Union at the salary you mention, I could not.

"When the districts about here are fairly divided, as they used to be when I came here, then my services shall be at your disposal for that formerly held by me.

"I remain, &c.,
"J. W. Lane, M.D.
"*The Board of Guardians, Clun Union.*"

Now this small portion, for which £20!! per annum is the salary, is, I should say, one of the worst to attend to, as some of the roads are not fit for travelling on horseback, and therefore you must walk. Of course my offer was not accepted, and how the poor are off I cannot say. This shows the greater necessity of a strong Central Board, who should have the power of appointments, and not leave such in the hands of parties who may, through being in power as "public bodies," make such the channel for venting their private malice, and the Central Board should consist of at least half medical men of some standing, who will see justice done to all.

I remain, Sir.
Faithfully yours,
J. W. Lane, M.D.
Bishop's Castle, Feb. 3, 1869.

◆

DESCRIPTION OF A NEW LIGAMENT.

O. Lannelong and A. Le Deutu—(*Arch. de Physiol. Norm. et Pathol.* 1. 448-450)—describe a ligament which arises from the posterior layer of the sheath of the sterno-thyroid muscle, inserts itself at the inner surface of the first rib, behind the sterno-clavicular articulation, and is thence continued to the anterior surface of the pericardium. This band includes the remains of the thymus gland. It serves to fix the pericardium at its anterior portion, and is the counterpart of the "ligamentum vertebro-pericardiacum," described by Béraud, which attaches the posterior surface of the pericardium to the spinal column.

ON THE EXHALATIONS FROM SWAMPS.

Prof. J. H. Salisbury communicates to the *American Journal of Medical Sciences* an elaborate article, giving an account of the numerous observations and investigations regarding the origin and cause of intermittent fever. Dr. Salisbury found on microscopic examination of the salivary secretions and expectorations of those labouring under intermittent fever, and who resided upon ague levels, and were exposed to the evening, night, and morning exhalations, and vapours arising from stagnant pools, swamps, and humid low grounds, that there occurred in these secretions a great variety of zoosporoid cells, animalcular bodies, diatoms, desmidieæ, algoid cells, and filaments, and fungoid spores. Constantly and uniformly found in all cases, and usually in great abundance, were minute oblong cells, either single or aggregated, consisting of a distinct nucleus surrounded by a minute cell-wall, with a high clear apparently empty space between the outside cell-wall and the nucleus. They were not fungoid, but cells of an algoid type, resembling strongly those of Palmellæ. In persons residing above the summit plain of ague, these bodies were invariably absent. By a series of carefully conducted experiments and observations the following facts were ascertained:—1. That cryptogami spores and other minute bodies are mainly elevated above the surface during night. That they rise and are suspended in the cold damp exhalations from the soil after the sun has set, and fall again to the earth after the sun rises. 2. That in the latitude of Ohio, these bodies seldom rise above from 35 to 60 feet; above the lowlands. In the northern and central portions of the State they rise from 35 to 45 feet; in the southern from 40 to 60 feet. 3. That at Nashville and Memphis they rise from 60 to 100 feet and more above the surface. 4. That above the summit plane of the cool night exhalations, these bodies do not rise, and intermittents do not extend. 5. That the day air of malarial districts is quite free from palmelloid spores and from causes that produce intermittents. Palmellæ belong to the lowest known vegetable organism; the several forms of this type which are constantly attendant on intermittent malarial diseases have received the generic name gemiasma, of which Dr. Salisbury enumerates six species. In another series of extended observations, the local effects produced in the mouth and air passages by inhaling these cells are minutely described. They cause a dry feverish constricted feeling in the mouth, fauces, and throat, increasing until the fauces become parched and feverish, normal mucous discharges become checked, and the feeling soon extends to the bronchial and pulmonary surfaces, which also become dry, feverish, and constricted, with a heavy congested sensation and dull pain. These peculiar symptoms generally last several hours after leaving the bog. The author has made experiments relative to the production of intermittent fever in localities entirely free from malarial influences, by carrying boxes filled with surface earth from a malarious drying prairie bog, covered with the palmellæ to these localities, and exposing persons to their emanations. Attacks of intermittents were the result. The investigations of Dr. Salisbury must be considered highly important, as they seem to establish positively the *fons et origo* of malarious fever.

EDUCATIONAL REFORM.—No. IX.

THE MEDICAL CURRICULUM.

If the requirements of the College of Physicians and the requirements of the College of Surgeons of England be added together, the product represents the curriculum which has to be passed through by the medical student who desires to obtain respectable medical and surgical qualifications. But on comparing the compulsory attendance on lectures, dissections, and practice exacted by these examining bodies, with the time allotted to performance, the very singular result is arrived at that, for at least the first eighteen months of the four years assigned to professional study, more work is demanded than can be accomplished in the time allowed for it. This was clearly shown by Mr. Rivington, in his "Remarks on the Necessity for a Revision of the Medical Curriculum," which paved the way for the important Report issued by the Council of the Medical Teachers' Association, on the alterations required in the present obligatory conditions of study. According to Mr. Rivington's calculation, which was "based on the physiological axiom that eight hours' work in the twenty-four is as much as can be expected from ordinary human beings, this compulsory attendance would take up eight hours every day for 468 days. In fifteen months there are 456 days—65 Sundays and 391 working days. Well, it might have been thought sufficient to provide for these 379 working days only; but, such is the pious and fostering care of the licensing bodies, that between them provision is made also for 89 days which do not exist. And so the work of these 89 non-existent days must be crammed into the midst of the 379 days which are already provided for, and provided for, be it observed, without any allowance for reading or sustaining life during the eight working hours."

In point of fact, conformity is impossible, and, most perniciously, the burden of choice and rejection of attendances is thrown upon the student, who often makes short work of the matter by not attending anything at all. He finds himself expected by the regulations to be learning, in the first eighteen months, the most incongruous subjects; to be acquiring a knowledge of the human body in disease before he knows anything about it in health; to be listening to instruction on diseases and injuries to parts of the body of which he scarcely knows the names, much less the composition and structure; to be involved in knotty questions of the causes of changes of which he is totally unacquainted with the nature and course; to be hearing harangues on scientific subjects which have little or no bearing upon the great object of his studies at the hospital; and to prove practically the error of one of Euclid's cardinal axioms by being in several places at the same time. This happy plan of mingling incongruous subjects; of allowing theoretically no time for private study; of compelling the body without regard to the effect of compulsion upon the mind; of exalting far above other educational instruments lectures, which the very conditions under which they are produced and delivered render liable to every possible defect; of allowing professors to wander at will over collateral subjects irrespectively of the end for which their partial cultivation was deemed desirable; of making regulations which, as those who have made them know, are not, cannot, will not, and ought not to be kept—is the outgrowth of that utter indifference to the medical profession as a corporate body which, from time immemorial, has distinguished the action of the Legislature and Ministers of the Crown. Partial evils have been met by partial remedies. Now a College has been created, and now an Apothecaries' Hall, neither "born great," nor having "achieved greatness," has had greatness "thrust upon it." Then a University has sprung up, and been endowed with the power of granting medical degrees and licences. Each of these and other similar institutions is allowed to possess the power of making any conditions it pleases for its diplomas; and as each issues its regulations in accordance with the particular ideas, more or less liberal, and the motives, more or less lofty, of its Executive Council, we arrive at last at arrangements which are exceedingly inconvenient to aspirants to the medical profession, as well as inimical to the production of first-class teaching powers. Finally, as a sop to a discontented Cerberus whose utterances are becoming too clamorous, up rises a Council, obtained by a distillation of the most conservative elements of the corporations, armed with a merely permissive authority, of construction necessarily loquacious and expensive, and as little representative as possible of the profession whose destinies its deliberations and decisions must materially influence and control. The glorious liberty of Britons, the abhorrence of centralization, the passion for little local centres of self-government and small pettifogging institutions, the aversion to comprehensive legislation on behalf of the medical profession, for fear of disturbing the flock of quacks which exist in our midst, fostered by the credulity and ignorance of the community which they fleece; the absence of the faculty of organization have brought us in the nineteenth century to this pass. We have now to recur to first principles, and to mould out of existing institutions, stubborn and inflexible as they have grown by dint of the possession of exclusive privileges, lucrative perquisites, and close constitutions, that simple machinery which could have been produced with the greatest ease with a fair field and no favour before us. We have to retrace our steps, and to win back our way until the light shall

> Break on this night of longing,
> Where hand in hand we grope,
> Through wastes of vain endeavour,
> 'Neath stars of fruitless hope.

The corporations can aid us if they will. We cannot expect them, of their own mere motion, to exhibit that single-mindedness which might imperil their sources of income and support; but we may reasonably ask them, under the condition of retaining their revenues intact, to adopt necessary measures of improvement. Cannot they simplify their schedules? Cannot they manumit the student from attendance on second courses of lectures? Cannot they abolish the regulations which compel the student to be attending practice before he has passed his first professional examinations? Cannot they remit compulsory attendance on courses of botany and elementary chemistry? Cannot they make the certificates of attendance on practice such as shall be guarantees of the possession of a certain amount of manual dexterity and skill in physical examination? Cannot the College of Surgeons throw overboard its obsolete objections to union with the College of Physicians in the conduct of a joint examination for a double qualification in medicine and surgery? These measures are not difficult of accomplishment, nor do they involve pecuniary loss. We fancy that we see the way clear to an ultimate saving for both Colleges by a diminution in the number of examiners. We are certain that the time demands that the College of Surgeons should no longer permit adhesion to a regulation contravening the intention of a recommendation of the Medical Council that there should be four years' professional study to stand in the way of joint action with the College of Physicians for the common good. But the act of union would be a work of time, while the other changes which we ask for may be accomplished speedily. Let the College of Physicians, let the College of Surgeons, let Apothecaries' Hall *at once* strike off the fetters. Let them *at once* reduce compulsory attendance to the limits of propriety and common sense. What are the liberal members of the executive councils of these bodies doing that we still find retained in their regulations compulsory attendance on *two* courses of anatomy, physiology, surgery, and medicine, and compulsory attendance on the wards and on clinical lectures before the first examinations have been passed? Pending the result of the sifting and weighing and searching which the principle of compulsory attendance will have to undergo, would not the supporters of compulsory attendance on lectures and practice act wisely by effecting the remissions which we are now advocating? Would they not strengthen their position instead of weakening it? And would not the radical reformers and undiscerning levellers lose some of their strongest arguments in favour of universal destruction? But, above all, would not the student be immensely benefited and relieved from regulations which are an excuse for neglect and deficiency of application to the idle dissenter, and real stumbling-blocks and blind guides to the industrious and conscientious conformist? That such alterations have not already taken place must be simply due to the circumstance that they have not been mooted in the councils of the licensing bodies. We cannot believe that if attendance on second courses of the same lectures on the same subject, were discussed in the Council of the College of Surgeons, or in the Council of the College of Physicians, a majority would not be in favour of remission of one of the courses. We cannot believe that there would not be a similar majority in favour of abolishing regulations compelling attendance on practice before the first examinations have been passed. We will pass over our other suggestions, and adhere to these two. If any Councillor is on our side, why does he not do battle in the cause? What are the Councillors of the College of Surgeons elected last year under the banner of reform doing to prove their sincerity? For what is Mr. Simon waiting? Is he expecting the arrival of his altered Report from the Medical Teachers' Association, and has he retired, like Achilles, to his tent? It is the part of wisdom to be content with gradual results, with partial achievements, with a succession of small conquests when complete success is not possible at a single stroke. "In all negotiations of difficulty a man may not look to sow and reap at once, but must prepare business, and so ripen it by degrees."

◆

PAUPERISM AND ITS CAUSES.

The question of Pauperism is, alas! the question of the day. All other topics seem of but little importance in comparison with it. Hence, we see that meetings are talked of in all quarters, to discuss the all-absorbing subject of what is to be done with our poor, and especially with our sick and poor brethren. "The poor ye have always with you," is a constant saying of some, when we wish to discuss the question. Let us once for all say that, did we believe in this literally, we should despair of the future of the race, and betake ourselves to scepticism and enjoyment of the hour. To admit, as some seem, especially our Conservative friends, that poverty is always to exist, is to admit that human science and human forethought are of no avail. A million of paupers out of 20,000,000 inhabitants in England and Wales! It is disgraceful to the intelligence of the age. The country which produced the illustrious Malthus, and in the language of which Adam Smith, Ricardo James and J. S. Mill, have written their immortal works, is still perhaps more grievously smitten with the dire curse of poverty than any of the European States at the present moment. France has no such an army of paupers as ourselves; neither has Prussia, nor any other of the German States. To such an extremity are we arrived, that, in some districts the poor's-rates threaten to eat out of house and home the honest and industrious workman and shopkeeper, and, as in Poplar, to render it rather preferable for the struggling among them to enter the workhouse than to keep house any longer. How is it that we come to have such a wonderful state of affairs as this? Where is all our vain glory and boasting about our being the most remarkable people in the world gone to? Is this all our science can do for us? No! Of knowledge we believe we have plenty, at least those who are acquainted with the question have enough knowledge to cure, nay, to prevent the recurrence of such a state of affairs. Unfortunately for us, every person thinks he can talk about poverty without studying the science which investigates the subject of wealth, viz. political economy. We are not surprised at this in the uneducated multitude, but confess to some little amazement when we hear the ignorance of that science betrayed by such gentlemen as Dr. Stallard and other members of our learned profession of medicine. What would Dr. Stallard or others, who speak so cavalierly of that most important component part of the science of society, political economy, say to the views of a person upon operative surgery, who had never studied anatomy or physiology? As to our own brethren of the priesthood, we beseech them to follow the noble examples of Whately and Chalmers, and, if they are anxious to tread in the footsteps of the Master, who said, "Love one another," let them remember that in order to perform that duty, they must know how to perform it according to the way in which Nature permits it to be done How ashamed Chalmers and Whately would have been of the meaningless tirades so often heard from the mouths of some "reverend brothers," about the hard-heartedness of the rich, and the wickedness of the poor! The cause—that is, the great cause—of the astounding poverty we at present wallow in, is, and is almost entirely ascribable to the fact, that this nation increases far too fast; and hence, although our towns are so unhealthy that the death-rate in them is often above 30 in 1,000 annually, whilst the mortality in country districts is frequently not more than half that figure, we are continually over-crowded, and our lower stratum pauperized, miserable, and degraded. Look at the number of infants that die of hardship and poverty annually. No less than 132 in 1,000 children die every year under the age of five in Liverpool, and only 33 in 1,000 in country parts. Look, too, at our emigration. More than 5,000,000 of our population left the shores of the British Islands, from 1815 up to 1855, or in forty years. Never was any emigration comparable to this in the history of the world. Our charities are most extended. The amount of gratuitous work done—among the poor, for example—by many a struggling medical man, is incredible, and injurious to the poor themselves, indeed tends to pauperize the whole of the community. And yet the modish benevolence of the moment talks always of new charity, and of new means of relieving the deserving poor. Now, we must just say for our ownselves, we should not like to have charity given to us, and why? Because charity means that we are of no use, *i.e.*, that we can do so little that any labour of ours is not worth anything, and that some other person is to work both for us and for himself. What a humiliating view of human nature is his who looks on charity as the solution of this great question! In a new country, such as the Western States of America, or in Australia, the work of every person is valuable, because there are few hands and much to do.

Are we never to arrive at such an earthly paradise on this side of the Atlantic? Is our science so paltry, our practical knowledge of the arts of life so slight, that we are always to have in our midst a number of persons who contribute nothing to the production of the country, although they desire to do so in order to live? Here is the solution of the difficulty, we believe. We have, it appears, very large families in this country; on an average, 4·5 children to each couple. Now, if so many are born, they must have some fate or other. Many die in towns before they reach the age of five; many of consumption and fevers from the wretched fare they live on and the bad air they breathe; many emigrate: and yet, so great is the number of births, that the capital we possess is only capable of maintaining a certain proportion of the remainder, and is inadequate to prevent some of us from relying on the charity of our more fortunate countrymen.

Have we realized how rapidly our race has the power of doubling its numbers? Chalmers believed that when people were supplied, *ad libitum*, with food, they could double their numbers in fifteen years. In twenty years this has several times taken place in new countries, as in the United States, from 1790 up to 1810, when the population, without counting emigrants, increased from 3,929,000 to 7,239,000, or nearly doubled itself. Supposing that some great discovery could enable us to get food as rapidly as in the Western States of America, our population could, if it liked, increase by the year 1889, to 60,000,000 in the British Islands. It is this tendency of ours to increase and multiply that keeps up our fatal and awful pauperism. Shall we, ere long, open our eyes to this fact? Is there enough of intelligence in our people to look it full in the face, and accept the hard fate which Nature has assigned to us, of either breeding very slowly, or being starved and dying like the lower animals? We know not how to reply to this. Certain it is that the illustrious Malthus not only discovered this most important of all facts about seventy years ago, but that his own work was admirably explanatory of the theory, and that Mr. J. S. Mill and others have long and eloquently inveighed against the evils produced by large families, and yet, we have sciolism on all sides. On the other hand, we believe that the virtues of emigration are not so strongly insisted on nowadays as they used to be. That plan is a miserable palliative to the evils of over-population, and people begin to see that it is so. And there is every now and then an allusion, usually in the form of an invective, to the views of Malthus and Mill, showing that persons are not *all* ignorant that the cause of the poverty and pauperism which surrounds us is to be looked for in our "Large Family System." For example, Mr. Laurie, at the Dialectical Society, and Mr. Matthew Arnold, in the "Cornhill Magazine," have both expressed themselves manfully as being utterly opposed to the British Philistine, with his large family and his conceited assumption that *his breed*, as Sir William Wilde amusingly terms it, can never be too numerous. The most pointed expression, however, is that of Mr. J. S. Mill, the greatest of living writers on philosophy and political economy. In p. 227 of his work "On the Principles of Political Economy," he says:—"Little improvement can be expected in morality until the producing of large families is regarded with the same feelings as drunkenness, or any other physical excess; but, while the aristocracy and clergy are foremost to set the example of this species of incontinence, what can be expected from the poor?"

This view of the cause of pauperism is so trenchant, so *positive*, that, until the assertions made by Malthus, Say, Chalmers, Whately, and the Mills, be met by a denial, it is of course needless to meet any side issue. Either pauperism *is* caused by large families, or it is *not*. If it is, then that error should first be set right; if it is not, then the science of political economy is a delusion, and the sooner we know this the better, and commence to build up a new science. For our ownselves we believe that the subject of the causes of poverty will soon come before the community for ventilation. And we have enough faith in the common sense of mankind to believe that such views as those we have endeavoured to explain in these few words will get a fair hearing. Bigotry and Puritanism are fast disappearing, and the *mauvaise honte*, or false shame, so peculiar to ourselves and our American cousins, is also much lessened, so that, although the subject is a delicate one, we doubt not that we shall not be content much longer to starve, as many of us have done, for want of a little patience and science.

SCOTLAND.

EDINBURGH.

The report of the Managers of the Royal Infirmary was read by the Secretary at the annual meeting of the subscribers. On the whole, the state of things was satisfactory, and the Chairman considered that by the economy they had practised an example had been set to many of the more wealthy and charitable institutions in the city. No deaths had occurred in Edinburgh from small-pox in 1868, showing the great benefit of the compulsory Vaccination Act.

EDINBURGH NEW TOWN DISPENSARY.

During the past year there have been 4,740 cases attended to at the dispensary, 3,768 patients treated in their own houses, 276 midwifery cases, and 818 vaccinations—making a total of 9,602 cases which have received the attention of the medical officers of the institution.

Mrs. Jean Johnston, Logan, amongst other legacies, has left £200 to the Glasgow Royal Infirmary.

St. Cuthbert's Parochial Board held their half-yearly meeting on the 2nd inst. In the report it was stated that the total number of lunatics chargeable to the parish in various asylums on 14th November was 210, being an increase of four on the six months, and a decrease of five as compared with the corresponding period last year. The sum paid for support of the lunatics during the six months was £1,837 15s. 2d., being an increase of £124 4s. 1d.

The Hawick Town Council met on the 2nd instant. The Provost stated that the trustees of the Scott Bequest Fund had offered £80 towards the establishment of an hospital and dispensary in the town. He thought it would be a great thing if such an institution could be had on a small scale, and suggested that the subject be submitted to the Sanitary Committee. On the subject of the drainage of the burgh, after some discussion, during which figures were quoted to show that the death-rate had very sensibly decreased of late years, it was agreed that underground sewerage be not proceeded with at present.

THE SCOTTISH UNIVERSITY SYSTEM.

Mr. Moncrieff's speech at his installation as Lord Rector of the University of Edinburgh brings forward again the comparative merits of the English and Scottish University system. Few only of those who most warmly advocate the English system have been so blinded by prejudice as to see no value in that prevailing in Scotland. It is easy to understand that many like the idea of domestic discipline which leads to the Oxford and Cambridge restrictions, while the laxity of that discipline, or the impossibility of thoroughly carrying it out, has to others been worse than nothing at all. On the other hand, the freedom, "the touch of nature" to be found in the "bare garret up three stories," which so pleases Mr. Moncrieff in the Scottish student's "home," has more reality and more romance in it, and is a better preparation for an active career than the most luxurious College life can compass. Young men cannot help feeling a kind of growth when they are called upon to think and act for themselves, to provide for their own wants, to measure their liabilities, perhaps to economize for the sake of completing their education, instead of being placed in a sphere where they must live in a certain style, and cannot control certain expenses. We can conceive no better education—using the term in its broad sense—than that which the student bestows on himself, who with the goal before him of a liberal education, casts away all encumbrances, denies himself needless luxuries, curtails his comforts, steadily restricts his expenditure, learns to despise the vanities and follies of fashion and style, and, by dint of steady industry, achieves his end. Such a man will be fit for any position in which he may be placed. He will have philosophy enough to support an earnest, quiet performance of humble duties, and independence and spirit enough to rely upon himself for success. Modification perhaps may be found advisable, but certainly the principle of liberty for University students is not likely to be infringed. It has worked well; it has turned out armies of young men, many of whom have won the laurel, and all of whom have worthily borne the burden and the heat of the day.

Mr. Moncrieff spoke also of the unsectarian character of the Scottish Universities, in a manner that shows how thoroughly he appreciates this "brightest jewel." He threw back the charge of bigotry with which we are so often taunted, in a manner worthy of his position as Lord Rector of the University of Edinburgh, Member of Parliment for the sister institutions of Glasgow and Aberdeen, Lord Advocate, Dean of the Faculty of Advocates, and leader of the Scottish Liberals. A "bigoted people" indeed! Our southern friends who so often repeat the taunt should, as Lord Advocate Moncrieff observed, "judge us by that crucial test of bigotry—education." When they have opened wide to all comers the gates of knowledge, that they now suffer to be guarded by sectaries, it will be time enough to talk of our intolerance. Catholic or Protestant, Churchman or Dissenter, it matters not to us, students of all races, all religions, all opinions, are welcome to come to the fountain of knowledge, to sit together under the same professors, to emulate each other in the same studies, and to carry on together a rivalry in learning which has proved beneficial alike to themselves and to the nation. It is this freedom, this unsectarian character of our Universities, which have attracted the attention of all, which have brought men of all creeds from other countries, to study and graduate here, and which, prior to the establishment of the University of London, afforded the only opportunity of obtaining a degree to those who could not give their assent and consent to the formularies of the established sect. This is the one reason why all English M.D.'s who are not churchmen came northwards for their degrees.

◆

GERMANY.

(From our own Correspondent.)

Vienna, January, 1869.

At the conclusion of my last letter, I commenced a few remarks on the specialists of Vienna by referring to Hebra, whose reputation as a dermatologist must be familiar to English as it is to all continental readers. As I see specialism attracts much attention here, it will be a good time to continue these notes.

I shall only allude to those men who are the acknowledged leaders, and whose scientific knowledge places them in the front rank of the army of diligent veteran doctors.

Amongst the specialists are to be particularly noticed the syphilographers, Sigmund and Herrman. They are antagonistic in most of their views. Dr. Sigmund, Professor of the Clinic of Syphilis at the Great Hospital, is the Ricord of Vienna. He employs the system of mercury and syphilisation, not excluding all other old or new remedies. Sigmund is one of the most clever professors; he was operator and head-surgeon of a large department of surgical cases in the Great Hospital. He is the son-in-law of the old celebrated chemist, Meissner (inventor of the plan of warming rooms by calorifères). He occupied himself very particularly with chemistry, and knows as well as anyone the qualities of the different mineral waters and climates of Europe, mostly by his own experience; and wrote a very good work "Southern Climatic Winter Resorts" ("Südliche Klimatische Kurorte").

Dr. Herrman is head-physician in the syphilitic section of the Hospital of Wieden, and his principle is, *no mercury*; and he is convinced that the diseases called, ordinarily, secondary syphilis, and tertiary syphilis, are nothing but *hydrargyrosis* or mercurialism, or abuse of mercury, because he has remarked just the same symptoms in the miners of Idria (the great mines of mercury), and never saw these signs in syphilitic persons who had made no use of mercury. Dr. Herrman employs in his treatment of syphilis iodine and gold in their different preparations, besides the principal remedies of the vegetable kingdom, and his results are as satisfactory as those of Dr. Sigmund.

There are two cliniques for surgery, and their heads are both eminent men. The one (the elder) is Professor Dumreicher, who was made a baronet for his merits in the war of 1866, in the campaign of Bohemia, at the battle of Sadowa. The other, Professor Billroth, was formerly at Zurich.

There is an Imperial institution (Josephinum), for military physicians and surgeons. There are also eminent professors. The most eminent operator and clinical professor of surgery is the counsellor Count Dr. Pithe, who was the head-surgeon in the Italian war of 1866, at the battle of Custozza.

The Professor of Anatomy, Engel, and the Professor Schneider, of chemistry, in the same Josephinum (called so after the founder, the immortal Emperor Joseph II.), are both eminent men in art and science.

The brightest star in the sky of the University of Vienna is Dr. Hyrtl, professor of human and comparative anatomy. His preparations and injections are the first in the world, and excited the highest admiration in each of the Exhibitions of London and Paris. He is member of the Academy of Sciences, and a rare example of combination of the greatest *savant* and the best and most popular teacher. His lectures are the most instructive, practical, and agreeable, which could be found. He knows how to interweave political, religious, and social questions, with dry anatomical demonstrations. He speaks a classical Latin.

Amongst the oculists, Dr. Taeger excels in diagnosis by means of the ophthalmoscope; Professor Arlt in his operations.

Amongst aurists, Dr. Gruber and Dr. Pollitzer must be mentioned. The latter is the originator of the simple mode of inflating the tympanum universally practised for both diagnosis and treatment by aural surgeons, and called after him Pollitzer's method.

One of the best schools, and the greatest credit to humanity, not only in Austria but in the whole of Europe, is the hospital and the two clinics for midwifery. Every pregnant woman (in the last three months), when poor and from very distant countries, is received in a special part of the hospital, and employed in little services towards other patients. They remain till the time of delivery; then they are received, like all other women in this period, at one of the two clinics, the one attended by the midwives and the other by the physicians (alternately one day the one, the next day the other). Students do not attend here, only qualified practitioners. For each clinic there is one professor, one assistant, and a head midwife. Each physician who attends the course is obliged to be present the whole day and night, when his turn comes; that is to say, for each arriving pregnant woman one physician is deputed according to the order of the inscription. The same method is followed in the clinic for midwifery. When a pregnant woman enters the room for reception, she is at once examined by the head midwife of the clinic, and if there are symptoms of approaching delivery one of the qualified student-physicians is deputed to remain at the bedside of the patient day and night, or at least not to leave the room, but to examine her from time to time to watch the course of the delivery. When there is nothing abnormal in the case, but all is right, the delivery takes place without the help of the assistant, whose apartment is in the middle of the clinique; but he is called immediately when there is an abnormity. After the delivery (six to twelve hours) the mother goes to the next room, a large saloon for puerperal women. If she is weak she is carried there with her child. She remains there from nine to fourteen days. On recovery she is removed to the institution for nursing mothers, where she may be called upon to partly suckle the child of one of the mothers who may have died in the hospital.

Notes on Current Topics.

Meat Preservation.

The preservation of meat by the aid of carbonic oxide gas, the process invented by Professor Gamgee, and which that gentleman is at present employed on in New York, was brought practically under the notice of the Society of Arts by Mr. Hardwicke on the 13th of last month. Previously to the meeting, a piece of beef and some mutton chops prepared by the process, having been cooked, were tasted by the members of the Committee present, who recorded their opinion that the beef and mutton were untainted and well preserved. Some members detected an acid taste in the beef, and others noticed nothing peculiar. The mutton was pronounced to be slightly flat. It was, however, the opinion of the Committee, that the mutton exhibited was of inferior quality of meat. Professor Gamgee's process is thus described in his patents:—"The animals are, when this is possible, killed by causing them to inhale carbonic oxide gas. The animals are then bled and dressed in the usual way, and the flesh may then be sold as human food, and even if it has travelled any distance it will retain a fresh and bright appearance longer than ordinary killed meat. The flesh may further be preserved as follows:—Firstly, by being placed in a closed chamber or vessel containing carbonic oxide gas alone, or a mixture of carbonic oxide and air for a period varying from two to twenty-four hours. Secondly, by simple fumigation of the entire carcase, after the action of carbonic oxide, by means of sulphurous acid gas alone or in combination with hydrochloric acid gas." Mr. Hardwicke informed the Committee that on the 4th December, 1868, Professor Gamgee, having had the animals killed in the manner described above, caused a large air-tight tank to be filled with two quarters of beef, two hams, eight sheep, and a large hog, when they were subjected to his process. This was done in New York. On the 12th the tank was opened, and the meat removed from it. On the 16th the carcases of four sheep, a quarter of beef, and half a hog, were wrapped in cloth separately, put into one large, rough packing-case, and forwarded to England by the Royal Mail-ship *Cuba*, arriving on the 30th. The meat exhibited was part of that so sent. The cost of preserving the carcase of a bullock was from 2s. to 3s. Professor Gamgee believed, from inquiries he had made, that the cost of transit would be considerably under a halfpenny per lb. He was informed, he said, that in Kansas a bullock in condition for killing could be purchased for £1, and to that had to be added the 3s. for curing and the cost of conveyance to this country. That would enable the meat to be sold at 3d. or 4d. per lb. here, and leave a good margin of profit to the adventurers.

The Naval Medical Service.

We read with much pleasure in the *Times* that the intention of abolishing the office of Director of the Medical Department of the Navy either never existed or has been abandoned. The degradation of the Medical Service to a mere branch of the executive would be a simple stultification of the policy to which Liberal Governments have hitherto adhered, and it would, we believe, be the last blow to the efficiency of this most important department of the Service, already sufficiently depreciated by the mismanagement of the Admiralty.

Remedies for Snakebites.

Professor Halford, of Melbourne, has recently been experimenting upon dogs in pursuance of his researches on the subject of snakebite. He has demonstrated very satisfactorily the good effect of injections of ammonia into the veins. His example has been quickly followed, Dr. Dempster, of Beechworth, having by this means brought about the recovery of a man who was bitten by a black snake. Dr. Dempster injected altogether into the saphena vein about twelve minims of the Liq. Ammoniæ Fortiss.

Inebriate Asylums.

The cause of the repentant drunkard is one which should enlist the heartfelt sympathies of the compassionate, and it is one to which we have devoted our pages from time to time with a most earnest desire that we might awaken the public attention to the subject. The condition of the unfortunate maniac is indeed pitiable, and the benevolent interference of the State is not wanting to the effort for his reclamation. Yet the hopelessness of cure in the majority of cases necessarily tends not to dull our humanity but to discourage our efforts. Why is it that we give no thought to the condition of the maniac—in whom our efforts may in all probability be rewarded by success—in whom the effects of the disease are reflected far and wide amongst innocent persons, and who craves our help to save him from the dominion of his own overpowering passions? Surely our much-placarded philanthropy is disgraced by the sight of tens of thousands of our countrymen hastening and dragging with them in their race their helpless families to present misery and future perdition, and by the fact that we are anticipated in a humane response to their appeal by the American people. In establishing Inebriate Asylums we would be entering on no doubtful speculation. The way has been shown to us, and the benefits well proven by the experiences of the New York State Asylum.

We learn from the *World* the following facts :—

Since May, 1867, when the new life of the Asylum began, 310 patients have been received, 230 of them coming in during the year which has lately closed. Of these 220 have been discharged and 82 remain. Of guests thus entertained 146 had wives and 164 unmarried, showing that celibacy is either an incentive to hard drinking, or that hard drinking causes men to avoid family responsibility. The habitual drunkards number 163, the periodical ones 147. Some came of themselves for voluntary relief ; others were brought by friends. Suffering from one or another form of delirium were 96 ; 34 had convulsions ; 73 were in general good health, but sought escape from the temptation that did so easily beset them ; and 101 were set down as cases in which this legacy of moral weakness had been inherited. After one trial of the beneficent influences of the Asylum, 113 left it thoroughly reformed. Eleven returned after one relapse, and four after a second. With no hope of retrieval 25 were expelled ; nothing definite could be ascertained about 68. Four died and three had to be transferred to the madhouse—insane beyond the chance of recovery.

Is it not a noble work of the State to send out the eleven out of every twelve of these pests of society, whom it has been enabled to reclaim, as good citizens and reformed members of society? and would not the sacrifice of labour and expense be amply justified even on the score of hard economy?

Statistics of the Profession in Prussia.

At the end of the year 1867, the following was the proportion of doctors in the principal towns of Prussia :—

Berlin -	- 649	doctors, or	1	per	973	of population.
Breslau -	- 224	„	1	„	731	„
Cologne -	- 114	„	1	„	1,071	„
Kœnigsburg	- 114	„	1	„	922	„
Magdeburg	- 73	„	1	„	1,117	„
Hanover -	- 97	„	1	„	800	„
Frankfort -	- 113	„	1	„	692	„
Dantzig -	- 64	„	1	„	1,220	„
Stettin -	- 53	„	1	„	1,335	„
Aix-la-Chapelle	53	„	1	„	1,204	„
Elberfeld -	- 21	„	1	„	2,952	„

—(*Annales de la Société de Médecine d'Anvers.*)

The following are the subjects for the essays for which prizes will be awarded by the Imperial Academy of Medicine during the ensuing year :—

Academy Prize. — Traumatic intracranial effusions. 1,000 francs.

Portal Prize.—The state of the bones, especially of the vertebræ, in cases of visceral cancer. 1,000 francs.

Madame Bernard's Prize.—Can neurosis be diathetic? and, if so, point out the special characters which diathesis impresses upon each neurosis. 800 francs.

Barbier Prize.—For the discovery of means tending towards the cure of diseases considered incurable, such as hydrophobia, cancer, epilepsy, scrofula, typhus, and cholera. 3,000 francs.

Capuron Prize. — The precursory and concomitant phenomena of milk secretion. 1,000 francs.

Godard Prize.—For the best work on internal pathology. 1,000 francs.

Orfila Prize.—Digitaline, its isolation and chemical tests. What pathological changes result from poisoning by it? 6,000 francs.

Itard Prize.—For the best book or memoir on practical medicine or applied therapeutics, published more than two years ago. 2,700 francs.

Lavison Prize. — For the establishment of exact and sufficiently numerous facts in men or animals who have passed from one climate to another, the modifications, alterations of function and organic lesions, which are attributable to acclimatation. 2,000 francs.

Ourches Prize.—For the discovery of a simple means of recognizing with certainty the signs of actual death, such as may be capable of being put in practice by uneducated persons. 20,000 francs.

For the discovery of means for the same object, such as galvanism, electricity, or other procedure requiring the aid of an educated person. 5,000 francs.

Saint Lager Prize.—For the experimentalist who may, by the administration to animals of the waters of a country in which goître is endemic, produce a thyroid tumour.

Excision of a Tumour.

The following interesting case has been forwarded to us for publication :—William Lee, aged forty-eight years, from Knockadea, had a fatty tumour weighing two pounds and the growth of over three years, successfully cut out from below the right hip last week by Dr. O'Connell of Kilmallock, ably assisted by Dr. Bennett, of Bruff. The patient is now out of all danger. The tumour is preserved and to be sent off to a museum.

The Preliminary Examination of the Royal College of Surgeons in Ireland.

The Council of the College at their last meeting decided, in compliance with the recommendation of the General Medical Council, on extending their curriculum in general education. The resolution of the Medical Council passed on the of , provided that after the expiration of the year 1868 no certificate of preliminary examination should be received unless it set forth that the candidate had been examined in geometry (the first two books of Euclid) and algebra (to simple equations). The College has therefore added these subjects to their examinations, and all students who commenced their education subsequently to 1865 will be required to answer in them at future examinations.

The Royal College of Surgeons in Ireland deserves the credit of having been in advance of the requirements of the Medical Council in the matter of preliminary education, for they have for very many years required from their candidates a knowledge of the Greek language, which has only last year been adopted by the Medical Council, and which will not be compulsory until the year 1871.

University of Cambridge.

The authorities of Trinity College have determined to give henceforth a Fellowship, once in three years, for proficiency in Natural Science. The examination will be open to all graduates of the University whose standing after the B.A., B.M., or B.L. degree does not exceed three years.

It will take place at the usual time of the examination for the Fellows, *i.e.*, early in October.

Clare College offers a Scholarship for Natural Science of the value of £50 a year, tenable for three and a half years. The examination will take place on March 17, and will be open to all students who have not commenced residence in the University. Further information may be obtained from the Rev. W. Raynes, Tutor of the College.

King's College Hospital.

An appeal *ad misericordiam* has been made on behalf of this hospital, which the liberality of the public is not very likely to leave unanswered. The annual expenses of the hospital are nearly four times larger than its income, so that there is a continually increasing debt, and the possibility of the institution being so straightened as to reduce it below the mark at which the examining boards will recognize it as a school of medicine has been publicly hinted. This would be a great misfortune, for, in spite of the constitution and regulations of the college and hospital, they no doubt meet an educational want, and notwithstanding great dissatisfaction at the mode of appointing officers, the present professional staff is not to be surpassed. In the presence of the recent revelations about our charities, and the mode in which money is collected and distributed, it will be no matter of surprise if many of the hospitals should come short and feel more closely pinched than ever. It is useless to ignore this possibility, and it will not be advisable for an institution thus in debt to neglect revising its rules and re-arranging its management. King's has obtained a great position, but cannot afford to neglect the signs of the times. May her friends read them aright!

Cornell University.

Our readers will be pleased to learn that the first term of this new experimental institution has closed, and that the results are gratifying to its generous promoter and all friends of education. The co-operative system has been found to work perfectly, and many pupils have been able to maintain themselves while obtaining a complete education. It is probable that Mr. Cornell has solved a great problem for Brother Jonathan, and certainly all on this side of the Atlantic wish him God-speed in his work.

Drugs and American Finance.

From an official report laid before Congress by a "special Commissioner of the revenue," we learn that drugs and chemicals are very disproportionately taxed. A new duty is levied on nearly half of the articles thus classified, and the duties bear no relation to their value. It is said that on opium and the alkaloids the duties are so excessive that a brisk smuggling trade is in full operation. We cannot forget that this condition of things is likely to lead to great mischief by introducing drugs of inferior quality. Adulteration is likely to flourish where so much scope for it exists, and few things are more calamitous than the inability to secure the physician's advice with medicines of the best quality.

The Cost of Cancer Curing.

The profession has long made up its mind on the subject of cancer cures, and those who profess to effect them. The public seems likely to hear something, if we may judge from the following legal intelligence, extracted from the *Times* of the 26th ult., under the head "Court of Queen's Bench":—

EX PARTE FREWEN, IN THE MATTER OF ONE JOHN PATTISON, A MEDICAL PRACTITIONER.

This was an application on the part of Mr. Charles Hay Frewen, of Oakham (at one time a Member of Parliament, and at the last election a candidate), against one Dr. John Pattison, lately of 26, Welbeck street, Cavendish square, for a criminal information on account of certain letters and publications by him directed against Mr. Frewen, and alleged to be libellous and tending to a breach of the peace. The matter, which was rather of a peculiar nature, had arisen thus:—From the affidavits it appeared that in the latter part of the year 1866, Dr. Pattison was called in to attend Mrs. Frewen, who was suffering from cancer, and he attended her until the 9th of February, 1867, when she died. Dr. Pattison had already received the sum of 150 guineas for his attendance, but he claimed a further sum of 100 guineas, which was refused. In May, 1867, an action was commenced to recover that sum, as the balance of a claim of 250 guineas, but that action had not been prosecuted. Various letters, however, had been sent since by Dr. Pattison to Mr. Frewen, couched in terms extremely offensive, and casting upon him the reproach of shabby and disreputable conduct in disputing the demand made upon him. In one of these letters, moreover, in October, 1868, Dr. Pattison sent an account of the case of Mrs. Frewen, which he hinted that he intended to publish in a professional journal, entering into very painful details of the sufferings of the deceased lady. Mr. Frewen had, in the meantime, referred the doctor to his attorneys, and in order to free himself from the annoyance, he had returned the later letters through the dead-letter office. Upon this the defendant had sent them open, so that anybody could read them, and in his last letter threatened that he should have the next written upon cardboard and sent to Mr. Frewen's Club.

The Hon. George Denman, Q.C. (with him the Hon. Alfred Thesiger), on an affidavit of these statements, moved on behalf of Mr. Frewen for a rule for a criminal information against Dr. Pattison. The learned counsel said he had a difficulty in reading the statement of the case which the defendant threatened to publish, entering as it did into all the painful details of that most painful disease under which the deceased lady had suffered. But there was, he submitted, amply enough in the expressions used by the defendant towards Mr. Frewen to justify this application. They imputed to him the most shabby conduct in disputing this demand, although Mr. Frewen had already intimated that he was ready to meet it in any proper way. The language used towards him by the defendant was of the most offensive character, and he had actually sent his later letters open, so that anyone could read them, and he threatened that the next would be written on cardboard and sent to Mr. Frewen's Club.

The Lord Chief Justice.—You have stated quite enough, Mr. Denman, to entitle you to the rule.

Rule *nisi* for a criminal information against Dr. Pattison.

Snake Poisoning.

From time to time our readers are made aware of the efforts made to meet this accident, and of other investigations undertaken respecting it. They have heard that Professor Halford, of Melbourne, has bestowed much attention on the subject, and will, therefore, be prepared to hear that the plan which has seemed to him most likely to be effectual—the injection of ammonia into the veins—has at length been employed on the human subject with a satisfactory result. We believe a case has also been tried in New South Wales, but we have not yet received any particulars. It may be a question as to whether any part of the sum offered by the Indian Government for the discovery of a remedy for snake bites may not be fairly due to Prof. Halford. Here are some particulars of the successful case: A railway workman picked up on the line an apparently dead snake, left there by a fellow workman, who thought he had killed it. The head was crushed flat, and the serpent was without sign of life; but as the man who took it up was carelessly handling it, putting his finger to its crushed head, with the remark "that it would never bite again," all at once he became conscious that his finger was pricked. He threw down the snake, but from ignorance or carelessness went about his business as before. Becoming very drowsy he proceeded to lie down, previously telling one of his mates what had occurred. The latter immediately set about procuring medical assistance, but by the time it arrived the man was comatose, and his lower extremities paralyzed. Galvanism and other usual remedies were applied, but without effect. In this extremity the medical man first called in sent for Professor Halford, knowing that he had experimented on the effect produced on the blood corpuscles by the poison of the snake, and that by the injection of ammonia into the circulation through a vein he had counteracted the effect of the poison. The case to which he was called was so obviously a desperate one under ordinary treatment, that it could not be made worse by the trial, and the remedy was applied, as follows:—An incision was made through the skin, exposing the superficial radial vein, and the point of the syringe being introduced into the vein the injection (of ammonia) was completed. The beneficial effect was marvellous and immediate. From an almost pulseless state, and from a stupor verging on death, the patient speedily became conscious. The recovery was continuous, and we expect shortly to receive a full and detailed history of the case.

Since we commented some few weeks since upon Mr. Baker Brown's arrangement with his creditors, we have learnt, and are happy to state, that the instalment of five shillings in the pound, mentioned by us, was but a preliminary agreement, a provision having been officially made for the ultimate payment of the remaining fifteen shillings; the celerity of this latter payment being somewhat dependent upon the health and continued activity of Mr. Baker Brown.

The report which has been very widely circulated, that the Queen would this year open Parliament in person, has been semi-officially contradicted, the state of her Majesty's health being such as not to permit the exercise of her much-to-be-desired prerogative.

The Marquis de Moustier, late French Ambassador to this Court, and a statesman of acknowledged ability, has just died of heart disease. He had been in feeble health for some time, and the loss of office, under circumstances which were anything but creditable to some members of the French Cabinet, is thought to have pressed very heavily upon the mind of the deceased. His death occurred on Friday last.

We hear that the effect of the reductions in the Army Medical Staff will be so large that no fresh admissions to the service are likely to take place for a year, if not a longer time.—*Army and Navy Gazette.*

A conference will be held on Thursday next, in the rooms of the Society of Arts, at which his Grace the Archbishop of Canterbury will preside, on the subject of the prevention of pauperism and crime in the metropolis. The distinct question to be raised is "the expediency and means of obtaining united action on the part of managers and dispensers of private charity and of Poor-law relief in the metropolis."

The *Gazette des Hôpitaux* announces that subnitrate of bismuth has been employed in large doses with wonderful success in Algeria as a specific for dysentery.

At the Royal Institution on Thursday next, at 3 p.m., Dr. Foster will read a paper on "Involuntary Movements;" on Friday, at 8 p.m., Mr. Greville Williams, on "The Poisoners of the Sixteenth and Seventeenth Centuries;" and on Saturday, at 3 p.m., Professor Odling, on "Hydrogen and its Analogues."

We understand that representatives from the London Charities will hold a conference to-morrow at the rooms of the Society of Arts, in the Adelphi, on the subject of the prevention of pauperism and crime in the metropolis. The Archbishop of Canterbury has consented to preside

It is said that the Government has resolved to adopt the Universities Tests Abolition Bill of Sir John D. Coleridge.

A piece of plate and an address were presented to Dr. MacGowan, proprietor of the *Medical Mirror*, by the inhabitants of Martock, in consequence of his intended removal from that town. The testimonial consisted of a splendid silver épergne and plateau. The address, which expressed their regret at his leaving, and their appreciation of his kindness and liberality during his residence among them, contained 102 signatures.

The *Lincolnshire Chronicle* says:—We never knew more illness than there is at the present time in most, or we believe all the parishes around Spalding. No house escapes, and almost every inmate suffers. It is said by some to be a bad form of influenza.

Dr. Chadwick, in addition to £17,000 for charitable purposes, has presented a donation of £5,000 to the town of Bolton, where he long practised, for the erection of artizans' model dwellings, and an orphan asylum.

Mr. C. Southard, the acting sanitary inspector of Exeter, is endeavouring to provide the poorer inhabitants with better habitations. He believes, from what he has seen, that the evils of overcrowding can hardly be exaggerated.

The notes in the Registrar-General's Quarterly Return show that the increase of mortality, in almost every case where it has occurred and where a reason is assigned, has been the result of overcrowding, or bad dwellings, or neglect of cleanliness and sanitary precautions.

At a meeting on the 28th ult., the Royal College of Physicians resolved to have printed, immediately, 1600 copies of "The Nomenclature of Diseases."

A verdict of £1,000 was awarded to Mr. J. Angus, M.R.C.S., whose child was run over by one of the vans of the Great Northern Railway. The child's thigh was fractured, and two of his fingers obliged to be amputated.

The late John Carew, Esq., besides numerous bequests to his relatives, has left £400 to the Devon and Exeter Hospital; £100 to the Training College for Nurses; and £250 each to the Deaf and Dumb Institution, the Dispensary, the Blind Institution, and the Female Penitentiary.

Professor J. Ville has discovered that the waters of certain lakes in Tuscany contain a large proportion of sulphate of ammonia. The water also contains boric acid.

Literature.

A SYSTEM OF MEDICINE.[1]

In our former notice we confined our remarks for the most part to Volume I. of this remarkable collection of professional lore, edited so skilfully by Dr. Russell Reynolds. Volume II. is equally bulky, equally learned, and equally various. It contains some of the best essays that have lately appeared, and is a complete library in itself. Publishers and editor are alike to be congratulated on their *magnum opus*, and the profession will look with interest for the appearance of the next volume.

Our regrets at not having more space to devote to it are lessened by the fact that we shall often find opportunities of recurring to the individual contributions. These are their names:—First, under the head of Diseases of the Nervous System, we have both general and partial forms of disease. Under the former, which includes a list of eighteen, we may mention insanity, ecstacy, catalepsy, sunstroke, paralysis, hypochondriasis, hysteria, and others which will not fail to interest the readers; and under the second as many as twenty different forms, which will equally repay perusal.

The second part consists of Diseases of the Digestive System, such as disorders of function, neurosis of the stomach, ulcer and cancer of the stomach, with many others, followed by addenda and notes.

The new edition of Dr. Salter's excellent and well-known Treatise on Asthma[1] makes, with the appendix and tabulated cases, a goodly volume of 464 pages, remarkably well printed, and got up altogether in first-rate style.

Chapter I. is devoted to the various Theories of Asthma. In our perusal of this chapter we looked with interest to see what more was said for or against the theory that asthma may be caused by *paralysis* of the bronchial tubes.

Dr. Walshe has said, in his work on "Diseases of the Lungs and Heart," that "bronchial asthma may depend on a *plus* or a *minus* state of the contractibility of the muscular fibres of the bronchial tubes; in the former case it is spasmodic, in the latter paralytic."

Dr. Fuller also, page 366 of the second edition of his work on "Diseases of the Lungs," says, "There is a form of bronchial asthma in which there are strong reasons for doubting whether the symptoms are not attributable to paralysis, rather than to spasm, of the bronchial muscles."

Such being the dicta of two eminent pulmonary pathologists, we naturally are anxious to hear what Dr. Salter says on the question of the paralytic theory of asthma.

Admitting that some of the phenomena of a fit of asthma might well be explained by assuming a paralytic state of the bronchial tubes (supposing these tubes to be engaged in expiration), yet Dr. Salter will not accept this explanation, for he denies that the bronchial tubes are agents of respiration.

"They *are* not, because they *cannot* be, agents of respiration (p. 21). There is one reason that, independent of many other considerations, forbids the possibility of it; it is that respiration is under the influence of the will, that it may be varied at pleasure—quick or slow, superficial or deep—while the contraction of the bronchial tubes, like that of all organic muscles, is essentially involuntary. This conclusive argument is well urged by Dr. Budd, in his paper on Emphysema and Asthma, in the Medico-Chirurgical Transactions."

We have not room here to quote the argument as set forth by Dr. Budd, and quoted by Dr. Salter at pages 22-23, but we must confess ourselves unconvinced, and still adherent to the belief that there may be such a disease as bronchial asthma due to a more or less paralysed condition of the muscles of the bronchial tubes. We should think that few would deny the possibility of the muscular coat of the urinary bladder being affected, sometimes by paralysis, sometimes by spasm.

The muscular coat of the bladder is, like the bronchial muscles, composed of pale unstriped involuntary muscular fibres, and these, in the act of micturition, act very well in unison with certain voluntary muscles.

"In breathing" (says Dr. Budd), "however rapidly we perform this act, we perceive no difference in the ease with which successive acts of respiration are performed. This is a proof the most decisive, that the fibres of the bronchi have no independent rhythmical motions of contraction."—(Salter, p. 23.)

By analogous reasoning we might argue that the muscular coat of the bladder has no motion of contraction in expelling the urine, and we might deny the possibility of retention of urine from paralysis of the muscular coat of the bladder. As a question of therapeutics we believe those cases tending to paralysis of the bronchial muscle are the ones that get good from pure bracing air, galvanism, and small doses of strychnia or nux vomica.

The very able and masterly way in which various other theories of asthma are disposed of by our author is, to us, thoroughly convincing; but we cannot conclude that the *spasm* theory is the only true one, we cannot as yet give up the paralytic theory as an occasional cause of true asthma, independently of co-existent emphysema.

Dr. Salter's Chapters on the Pathology, Ætiology, and Phenomena of Asthma, are most interesting, and contain much that is new and the result of careful observation and study.

Much space is wisely assigned to the treatment of asthma, both during the paroxysm and in the intervals. Rules for treatment by diet, by climate and locality, by stimulants, sedatives, and medicines generally, are given concisely and in a way that shows the author to be no mere theorist, but one constantly handling and using the means of cure that he recommends to his readers.

Finally, the appendix of narrative cases, of which there are goodly number, illustrating peculiar forms of asthma—as, for example, hay asthma, cat asthma, ipecacuan asthma, &c.—form matter both interesting and entertaining to the reader.

---

[1] A System of Medicine. Edited by Russell Reynolds, M.D. London: Macmillan and Co.

[1] Asthma: its Pathology and Treatment. By Henry Hyde Salter, M.D., F.R.S., Fellow of the Royal College of Physicians; Physician to Charing-cross Hospital, and Lecturer on the Practice of Medicine in the Medical School of the Hospital. Second Edition. Churchill, New Burlington street.

We must not omit to notice the 223 tabulated cases, against the comparatively small number of 44 in Dr. Salter's first edition. The work of tabulation, done as these cases are done, must have been very arduous; but the results are well worth the labour, and help to render complete certainly one of the best treatises on asthma that we have ever opened in any language.

HOSPITAL REPORTS.[1]

We have often remarked on the impossibility of doing justice to the volumes issued by the various hospitals, and last year made use of some of these by condensing cases—a plan we may try again. The two volumes before us are worthy of the schools that produce them. In the first will be found some of the more finished essays of metropolitan teachers; in the second, similar contributions from provincial men.

Summary of Science.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

(Specially Edited and Compiled for the Medical Press and Circular.)

By C. R. C. TICHBORNE, F.C.S., F.R.G S.I., etc.

ON THE MODE OF SEARCH FOR STRYCHNINE IN A CASE OF POISONING.

M. Cloetta proceeds as follows when wishing to determine the presence of strychnine in blood, urine, or animal tissues:—The liquid to be examined is purified by the addition of sub-acetate of lead. The filtrate is deprived of the excess of lead by sulphuretted hydrogen, refiltered, and then evaporated to dryness. The residue is treated with ammonia for twenty-four hours, agitated with double its volume of chloroform, and the chloroform solution evaporated to dryness. The residue from this evaporation is then treated with two centimetres of water, acidulated with nitric acid; to this is added a drop of a solution of bichromate of potassium. After some hours it deposits crystals, visible to the eye, of chromate of strychnine; with the aid of a microscope the characteristics of the salt may be determined. M. Cloetta can show, by manipulating in this manner, the presence of 1-20th of a grain of strychnine in 650 centimetres of urine.

COLCHICINE.

Colchicine is an amorphous powder of a yellow colour. It has little or no odour, but a very bitter taste. It is a very feeble base, but still restores the colour of red litmus paper. The most characteristic peculiarities of this alkaloid are—1stly, a violet, or blue colouration, which it takes with oxidizing agents—such as a mixture of sulphuric and nitric acid; 2ndly, weak acid produces a yellow; alkalies affect it in a similar manner. The iodomercuriate of potassium precipitates it, even when the alkaloid is dissolved in 27,700 times its weight of water. Tannin and phosphomolybidic acid also precipitate it. The colchicine forms salts with acids, but they are rapidly changed into a mixture of resin and colchiceine. In preparing this substance, it is, therefore, necessary to avoid the action of acids, or alkalies, and it is also necessary to manipulate in the cold. It was impossible to find glucose amongst the products of decomposition of colchicine after the transformation of this alkaloid into resin and colchiceine. (M. Maisch, *Mon. Scient.*)

VAPOUR DENSITY OF CHLORIDE OF AMMONIUM.

M. Marignac has attempted to determine the latent heat of the volatilization of sal ammoniac, with a view to determine this vexed question. He considers the results of his experiments to be only a crude approximation, but sufficiently accurate for the purpose. He endeavoured to measure the amount of heat consumed in volatilizing the salt. A large cylinder of iron is supported in a case, the sides of which are made bad conductors. The iron cylinder is heated red hot. When the cylinder has cooled down to a certain temperature (500°), the substance to be volatilized, enclosed in a silver or glass tube, is introduced. The tubes are withdrawn when the thermometer marks 420°. The loss of weight gives the amount volatilized. Comparative experiments made with this apparatus, without and with substances, enable a calculation to be made. Operating with sal ammonia, the largeness of the number compared to that which expresses the latent heats of volatilization and its concordance with that which expresses the heat from ammoniacal gas and hydrochloric acid, prove, says M. Marignac, that sal ammoniac is partially decomposed when converted into vapour. There is little doubt that this is correct, but that the decomposition is only partial. All recent experiments have joined to prove this view, and thus the anomalous vapour density of chloride of ammonia is accounted for.

SCHONBEIN'S TEST FOR HYDROCYANIC ACID.

This test, which is stated to be one of the most delicate, is made in the following manner:—

Three grammes of guaicum resin are dissolved in 100 grammes of alcohol. Pure filtering paper is then dipped in the solution. This paper ought to remain white. A second solution is then made by dissolving 2-1000 of a decigramme of this salt in 50 grammes of water. When it is intended to test for hydrocyanic acid, a little fillet of the guiacum paper is moistened with the solution of sulphate of copper, and brought into contact with the substance to be tested. It does not matter whether the hydrocyanic acid is dissolved in water or is present in the air, the paper becomes blue immediately.

CREATININE IN PUTREFIED MILK.

M. Commaille submitted skimmed milk to putrefactive fermentation in a vessel closed by a piece of paper. The liquid, on filtering and evaporating, yielded, by successive treatment with alcohols of different strengths, crystals containing a considerable quantity of mineral substance. These crystals, when dissolved and treated with nitrate of silver, gave a voluminous cheesy precipitate, which, when treated with boiling water, yielded a small quantity of needle-shaped crystals, which proved to be nitrate of creatinine. The double nitrate of silver and creatine, and the double chloride of zinc and creatinine, were formed. It is therefore probable that the milk is like urine, in which, if left to the air for some weeks, no creatine can be found—only creatinine.

Creatine is found much more frequently in fresh animal substances than creatinine. Creatine has not been recognized in milk because of the large quantities of things with which it is associated. The author then states that it is necessary to consider creatine as one of the constituents of milk. He gives the following as the composition of that substance according to our present knowledge.

Fatty matter	Butter.
Albuminoid substances	1. lacto-albumin. 2. caseine.
Pseudoprotein matter ...	Lactoprotein.
Crystallizable nitrogenous matter (amines)	1. urea. 2. creatine.
Organic acids (little known) ...	
Colouring matter and odorous substance	
Mineral matter	
Sugar (very abundant)	Sugar of milk, or lactine.

Journal de Pharmacie et de Ch.

INFLUENCE OF COLOURED RAYS ON PLANTS.

The Paris correspondent of the *Chemical News* mentions some experiments by M. Cailletet "On the Influence of Various Coloured Rays on the Decomposition of Carbonic Acid by Plants." M. Cailletet makes use of coloured glass bells.

Leaves of the same plant, and of equal surface, decompose the same volume of carbonic acid when they act on identical gaseous mixtures, and exposed to the same luminous source.

Coloured leaves* nearly always contain a certain quantity of chlorophyll, but decompose carbonic acid slowly; whilst the white part of the leaves of the *aspidestra elatior* and such plants are without decomposing action.

The absorption of carbonic acid and the disengagement of oxygen, more or less mixed with nitrogen, appertain exclusively to the parts of the plants which contain the green matter. The rays were passed through a concentrated solution of iodine in bisulphide of carbon. This solution was only permeable to the obscure rays of heat. Carbonic acid, mixed with air, suffered no decomposition, notwithstanding the prolonged action of solar rays. The divers coloured rays have, on the contrary, a special action, more or less powerful, on the dissociation of carbonic acid. From an inspection of M. Cailletet's tables it would seem that the coloured rays which favour most chemical decomposition (as regards chloride of silver) are those that favour decomposition of carbonic acid the least. Yellow induces the largest decomposition and red next.

---

[1] St. Bartholomew's Hospital Reports. Vol. I.—Liverpool Medical and Surgical Reports. Vol. II.

* A remarkable exception to this fact was shown by Mr. Tichborne to exist in the leaves of the Virginian creeper and similar plants. The red leaves of this plant do not show the chlorophyll bands.

PURIFICATION OF SULPHIDE OF CARBON.

M. Millon purifies sulphide of carbon by washing repeatedly with distilled water; it is then placed in a large vessel upon quick lime. After twenty-four hours' maceration, it is distilled from the lime. It is then received upon turning of copper, previously heated, and again reduced by hydrogen. The object of this being to destroy the fatty matter with which it is contaminated.

The bisulphide of carbon, formed in this manner, has an ætherial odour, which is not very agreeable, but which is very different from the fluid which is ordinarily known under that name.

This bisulphide is used by M. Millon to extract the odour of delicate flowers.

FORMATIONS OF ARTIFICIAL MINERALS.

M. Becquerel has endeavoured to get the hydrated minerals by the use of parchment paper. In a vessel formed of this paper he placed aluminate of potash, and plunged this into a solution of nitrate of copper. The nitrate of potash is produced; but instead of aluminate of copper in the paper vessels, crystals of hydrate of alumina are formed, and in the other vessel, crystals of hydrate of oxide of copper are produced.

If the aluminate of potash is replaced by silicates, hydrated silica is obtained, hard enough to scratch glass.

Gleanings in Medicine, Surgery, and the Allied Sciences.

CASE OF GASTROTOMY.

Dr. Henry T. Fox reports the following case in the *Australian Medical Journal*:—J. H. M., æt. 41, states that during the past eight months he has been suffering from increasing difficulty in swallowing his food. At this date when we first saw him, he could only swallow liquid, of which a small quantity percolated into the stomach, causing pain in its transit, while the remainder was soon after ejected. His account of the process of swallowing was very graphic, referring the stoppage to a point corresponding to the junction of the ensiform cartilage to the sternum, he said the food came against something on the left hand side of the passage and was forced towards the right, and then drop by drop found its way downward. Neither then not at any future time did he suffer from acute or darting pains, until within two or three weeks of his leaving the hospital. His body was in good condition, and his complexion clear and rather high coloured; careful examination revealed no indication of disease of the heart or large vessels, nor of the lungs. The account of falls which he had received, and of the subsequent hæmorrhage threw a doubt on the diagnosis of a scirrhous growth, and we did not think it judicious with the knowledge of that hæmorrhage to attempt the passage of a bougie, and perhaps open a track into a possible aneurism. The passage of food into the stomach became more and more obstructed, and at last the œsophagus was impervious even to a drop of water; he lost flesh very fast, and was evidently rapidly sinking. I visited him on the 23rd, he was very faint, and the pulse exceedingly feeble from the exertion of recently defæcaing, the first time he had passed anything from the bowels for three weeks. I found him well informed as to the dangers of gastrotomy, and that at best it offered only a means of temporarily ameliorating his sufferings. But knowing that he was still desirous of the operation, at half-past three p.m. I operated. I made a straight incision of about four inches in length in the course of the left linea semilunaris, beginning where that line commences at the intercostal cartilage. Having divided the various muscular and fibrous layers until the peritoneum was exposed, I raised that membrane with my dressing forceps, and made a small opening sufficient to introduce a director, on which I slid a sharp pointed curved bistoury, and divided the peritoneum for a distance corresponding to a little more than half the external wound. As this division exposed the stomach sufficiently for the subsequent proceedings, I did not extend the incision upwards, and consequently did not even see the left lobe of the liver, and it is worthy of note that the stomach was found without any difficulty, although it was much contracted. I fixed the organ with a small hook, and made an aperture in it about one inch and a quarter long, carefully including the punctures made by the hook in the line of the incision, and avoiding the vessels running along the great curvature. I next sewed first one side and then the other of this aperture to the corresponding edges of the external wound with a continuous suture; having completed this I secured the tails of the external wound with harelip pins, which were inserted as deeply as practicable without touching the peritoneum. The end of an elastic tube was now introduced, but from the contracted state of the stomach only to a very short extent, and some beef tea and wine were injected, but the bulk regurgitated by the sides of the tube, and he appeared to suffer more from this first injection of food than from any part of the operation. The tube was left in and the patient was removed to bed; during the operation he became rather faint and his pulse sank, but he soon rallied, and at the end of an hour was in good spirits, his pulse 100 with better volume; at this time I tried injecting milk, but a large proportion still escaped. 24th, 9 a.m. Has not slept much, is calm and sanguine, has a better pulse, tongue moist and clean though pale, has not allowed any injection of broth during the night; on my insisting on injecting some, no regurgitation ensued. 5 p.m. Going on well, quantity of urine much increased; removed the elastic tube, which was inconveniently long, and inserted a shorter one; this change was made without causing him any pain. 25th, 10 a.m. Has slept well, complains of slight cough, which renders him uneasy; in other respects doing well. 26th, 9½ a.m. He passed a very bad night, through the cough, pulse quick, urine high-coloured; the line of incision, which is united, shows a faint red margin. I did not remove the harelip pins, through fear that the agitation of coughing might break up the recent adhesions. He died on the 27th, at 4 a.m. The autopsy seven hours after death was necessarily very meagre. There was firm union in the tails of the incision, and the edges of the aperture in the stomach were adherent to the skin and subcutaneous tissue, but were readily torn apart with the handle of the knife. The peritoneal surface of the pyloric extremity of the stomach was covered with recent lymph, and the ascending colon was adherent to the parietes of the abdomen. On opening the œsophagus a scirrhous deposit was found occluding the passage for the space of about two inches; this mass did not descend nearer the cardiac orifice than half an inch, and was larger and more prominent on the left side than on the right.

HYDATID CYSTS OF THE LIVER.—THE IMPORTANCE OF THE VIBRATION AND MUSICAL NOTE IN DIAGNOSIS.

Dr. Keyes presented to the New York Pathological Society, on behalf of Dr. Van Buren, a quantity of hydatid cysts of the liver, discharged per rectum. In regard to the question of diagnosis, an important point came up for consideration, having reference to the existence of the hydatid vibration, and of the musical note described by Rayer and Briancon. None of the gentlemen present at the first examination, after the most repeated and careful trials, were able to make out the existence of either. In this connection Dr. Keyes stated that Briancon, who refers to the existence of the vibration and musical note as important, if not pathognomonic symptoms, had made a number of experiments with bladders partially filled with fluid and hydatid cysts, and had found that when the hydatids were slightly in excess of the fluid, the vibration and musical note were most distinct, but that they decreased in intensity to absolute disappearance, in proportion to the relative excess of the fluid. The examination of the contents of the cysts by the microscope disclosed nothing but the presence of the hooks of the echinococcus. The fluid contained no albumen.

BIRTH OF AN EXTRAORDINARILY LARGE CHILD.

Dr. Brotherston, of Alloa, communicated to the *Edinburgh Obstetrical Society*, the following record of the birth of a gigantic fœtus:—I was called upon Wednesday morning last, about half-past five, to attend on Mrs. F., Alloa, who was in labour with her seventh child. Matters went on as usual till the head was expelled, and I expected that the next pain or so would terminate the delivery; but, on the contrary, though the pains were severe, and I applied a moderate degree of traction to the head during nearly twenty minutes, I could not deliver the body of the child; the shoulders appeared to be the obstacle, and the right arm-pit could be reached by the finger without much difficulty. I sent for Dr. Duncanson, who came immediately, and he brought my instruments with him; we then applied the blunt hook to the right axilla, and, by traction of no ordinary kind, extracted a dead male child of the following dimensions:—Weight, 17 lbs.; length 23½ inches; circumference round the head over the occipital and frontal prominences, 15 inches; circumference around shoulders, 20 inches; circumference around chest, 15½ inches; circumference around stomach, 17 inches; from funis to sole of foot, 10½ inches; from funis to head, 13 inches; circumference of thigh, 9 inches; length of leg from trochanter to heel, 10½ inches; length of arm, 10 inches. The measurements were taken in my presence by Dr. Duncanson and Mr. F., the father of the child. Mrs. F. is making a very favourable recovery. The father is six feet high,—a very proportionate man, and rather good-looking, aged 44; weight 13 stone. The mother is 5 feet,—rather stout, aged 40,—was never weighed, but looks about 11½ stone. The child was perfectly formed in every way—no signs of hydrocephalus whatever. This will be seen by the measurement of the head, which was 15 inches, and well formed. The child was living when the head was expelled from the pelvis and vulva, as it gave a convulsive effort, as if trying to pull back the head occasionally. This lasted, I think, about ten minutes. When these efforts went off, I believe the child died. I suppose the cause of death was pressure of the cord, the body of the child being of such a size as to effect this most readily. When the child was extracted, it was quite dead; its right humerus gave way near the neck, from the pressure of the blunt hook. There was no hæmorrhage afterwards worth mentioning—just what is usual. Dr. Keiller thought this was about the heaviest child he had ever heard of. He had shown a fœtus some time ago, which had been delivered by craniotomy, and whose shoulders were so large that great difficulty had been caused in extraction. Even now, although preserved in spirit for such a length of time, this child still looked a giant, but he did not think it would weigh more than 14 lbs. He had heard of an American baby which weighed 19½ lbs. at birth. Dr. Pattison said there was a child in Dr. Thatcher's museum which weighed 16 lbs.

CIRCUMSTANCES WHICH RENDER THE USE OF TIN VESSELS NOXIOUS.

Dr. Delahaye observed in 1866-67, during the hot weather, in many old patients in hospital, all the usual symptoms of lead-poisoning. He searched everywhere for the cause of these phenomena, and his attention was at last attracted by the tin tankards in which the old men kept their cider at hand all day, to quench the thirst, which resulted from the oppressive heat. The analysis proved that the cider in barrel was perfectly pure, although the reagents detected traces of lead in the liquid which had remained all day in the tin vessels. M. Delahaye concluded from these facts, of which he gave a succinct explanation—1. That under certain circumstances the lead which constitutes a certain part of the tinning of these vessels, may communicate poisonous properties to them. 2. That the phenomena are favoured by high temperature, which sets up acid fermentation—by the alcoholic habit, and by advanced age. 3. That in the cases of poisoning which he experienced, the mixture of sulphur and honey, prescribed by M. Lutz is very effectual, and that coffee as a nutriment is an excellent means of sustaining vital powers and combating the depression, which is observed in these cases.—*Journ. de Méd. et Chirurg. Pract.*

NOTICES TO CORRESPONDENTS.

Notice to Subscribers.—Subscriptions for the year ending Dec. 31st, 1868, are now due. Subscribers resident in England will greatly oblige by forwarding the usual amount, 22s. 6d., either by cheque or P.O.O., made payable to A. A. Tindall, 20 King William street, Strand, London.

Subscriptions in Ireland to be sent to 3 Lincoln place, Dublin, and in Scotland, to Maclachlan and Stewart, South Bridge, Edinburgh.

Advance subscriptions, 21s. 8d. post free per annum, for the current year, can also be paid as above.

THE SIAMESE TWINS.

To the Editor of the Medical Press and Circular.

Dear Sir,

I find that your printer has by implication led your readers to suppose that I am the *entrepreneur* who has taken in hand the Siamese Twins, whose advertisement appears in my column in the midst of my announcements. My friends may possibly give me credit for some versatility, but though I appear in public myself sometimes, I do all in my power to prevent the "public exhibitions" of my clients, whose business I seek to conduct in the most private and confidential manner. I am not, therefore, "the proprietor" of the Siamese Twins, who came to England to be *separated*; indeed, I am *uniting* my clients in bonds of partnership, which I trust may prove sufficiently advantageous to be permanent. My experience brings me into contact with many "wonderful living curiosities" amongst the members of my profession, but my duty is to draw the veil of charity over their failings and eccentricities, rather than allow them to "make their appearance" at the "Egyptian Hall," Mansion House, or any other Halls where medical students occasionally distinguish themselves, except the Apothecaries' Hall, where by the "Powers," I always wish them success.

Please, therefore, to put the Siamese Twins in their right place, and as a compensation for the mistake send me and my friends tickets of admission to examine those "wonderful living curiosities."

I am, yours truly,

J. Baxter Langley.

Dr. MacEvers (Cork).—It does not appear to us that the fact of Dr. Nedley being an estimable practitioner, or even a friend of our correspondent, Dr. MacEvers, is sufficient qualification for the office of physician to his Excellency the Lord-Lieutenant of Ireland. Our objection to Dr. Nedley's appointment on professional grounds would be equally applicable to hundreds of practitioners of equal mediocrity. We hold that it is a gross abuse of political patronage to confer upon an undistinguished and unheard of practitioner the post of honour for which claimants of equal political claim, and infinitely superior professional attainments were plentiful.

If Dr. MacEvers can favourthe profession with any single reason why Dr. Nedley should be preferred before Dr. Mapother, Dr. Lyons, Dr. Robert MacDonnel, or a score of other gentlemen of position, and with equivalent political claims, we shall be glad to hear him.

"A **Suggestion** for the Sanitary Improvement of Towns and Dwellings," by Dr. Z. Johnson, F R.C.S., &c., received.

Dr. J. Stuart Vesey.—Your communication on "Cancer of the Penis" will appear in an early number.

P. O.—The present series of "Medico-Social Pencillings" is nearly finished. If we find the majority of our readers approve of them, it is possible another series might be commenced, when the suggestions that if our "facetious writer would take up the charities and workhouses, he would do much good, as he can be grave as well as gay, and in a form that is open to impressions from either," and any other suggestion we may be favoured with, will be taken into consideration.

Communications with enclosures received from Mr. Erichsen, Dr. Williams, Fulham; Mr. J. Baker Brown, Mr. Pomfret, Hollingsworth; Mr. Cooper, Brentford: Dr. Percival, London; Dr. Atherton, Thatto heath; Mr. Rigg, Much Woolton; Dr. Furnival, Brompton; Dr. Verdon, London; Mr. Birchenall, Macclesfield; Mr. Dobbs, Newport; Dr. Johnson, London; Dr. Sedgwick, London; Mr. Tuckett, Clydash; Mr. Kiddle, Dr. Dowsland, Weaverthorpe; Mr. Cockcroft, Hurworth; Dr. Camps, London; Dr. Hunter, Aberdeen; Mr. Popjoy, Accrington; Dr. Jenner, Dr. Kiernan, Buckfastleigh; Mr. Daniell, Kegworth; Dr. C. Young, Yarm, Mr. Warnock, Birmingham: Dr. Morgan, Dublin; Dr. Lane, Bishop's Castle; Dr. Davys, Swords; Mr. Davies, H.M.S. WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Session 1868-9.

Dr. Thorowgood, on being elected President of the above named Society, gave the usual Introductory Address at the commencement of the present Session.

After complimenting the members on their satisfactory financial condition, the President proceeded to take a brief survey of the progress of Medical Science during the past twelve months. Allusion was first made to the doings of preventive medicine and sanitary science during the past year; the various epidemics of fever at Winterton, Guildford, and Terling were severally noticed as illustrations to show how distinctly these outbreaks of fever can be traced to imperfect drainage and pollution of the water supply, and how entirely preventible they are if people will but take reasonable precautions. Speaking on these subjects Dr. Thorowgood said:

"The outbreak of typhoid fever at Winterton in Lincolnshire, in the years 1865-66, particularly attacked a group of thirty-five houses at the west end of the town; and here within the twelve months, out of 145 inhabitants 100 contracted fever, and 17 died of it."

The next point adverted to was the late researches of Dr. Buchanan into the effects of subsoil drainage in diminishing the mortality from phthisis in several districts in England. It was shown by statistics that where efficient drainage had perceptibly dried the soil that the mortality from phthisis had diminished both too uniformly, and also in too great an amount to be regarded as an accidental coincidence. Thus the death-rates from phthisis in the fifteen under-mentioned towns had, after improved land drainage, fallen per centum as follow:—

Salisbury	49
Ely	47
Rugby	43
Banbury	41
Worthing	46
Leicester	32
Macclesfield	31
Newport	32
Cheltenham	26
Bristol	22
Dover	20
Warwick	19
Croydon	17
Cardiff	17
Merthyr	11

Passing from this subject to notice the improvements effected in the management of workhouses, and the good likely to accrue to the mercantile marine by the introduction of the Merchant Shipping Act of 1867, whereby a pure supply of genuine lime-juice is secured for the seamen in this service, the lecturer proceeded to speak of recent researches by Dr. Sanderson and Mr. Simon, on the inoculability of tubercle, as well as of the highly interesting experiments made by Dr. Thudichum on the chemistry of diseases as investigated by the spectroscope.

The concluding part of the address exhorted to a more diligent study of practical therapeutics, and was as follows:

Since the great business of us doctors is to cure people of the various ills to which they are liable, it becomes us, in looking back, to observe what advances have been made in our methods of dealing with the diseases and mishaps incident to human life.

In surgery we find the antiseptic treatment, brought prominently into notice by Professor Liston of Glasgow, to be steadily gaining ground; it seems as if now the tendency of surgeons was towards the practice of treating wounds by pouring in oil and wine, rather than by the water dressing once so highly commended for its simplicity and suitability to all kinds of wound or injury.

In illustration of the antiseptic plan allow me to relate briefly a case of Mr. Syme's in the Edinburgh Infirmary.

On the morning of August 10th, J. Dart, æt. 53, going out to cut grass about 30 miles from Edinburgh, fell upon his scythe and inflicted a severe wound of his knee-joint.

He was put into a cart and taken to a station, whence he travelled by rail to Edinburgh. It then appeared that a wound four inches long extended obliquely across the knee, dividing the quadriceps extensor tendon, and affording free access to the joint. The cavity was freely sponged with carbolic acid; the cut edges, which had been widely separated, were drawn together by sutures; a pledget of carbolic oil was placed over the wound, and a splint was applied to keep the limb straight. Not the slightest constitutional or local disturbance followed, the pulse never rose beyond 63, on the fourth day the wound was healed, and on September 13th the patient left the hospital with the limb strong and flexible.

At the Great Northern Hospital Mr. Adams has had many very successful results in cases of wounds and compound fractures by following the principles of the antiseptic treatment; all wounds are washed with ether, either at once, or after a preliminary cleansing by water.

Thus we see surgeons coming now once again to a sort of modification of the old-fashioned "vulneraries" with which they used to treat wounds years ago.

As in surgery, so in physic, we are tending now, I believe, much more towards a positive system of drug healing than we were even a few years ago, when the expectant school was so active in teaching, that people got well whether they had drugs, or whether they had not, and often a deal faster without them than with them.

This expectant school of physicians unquestionably formed a most wholesome reaction against the ridiculous polypharmacy and rude farrier-like practice of wholesale bleeding, which had been so much in vogue previously, and which was often the destruction of the patient; but it is contrary to all we know of man and his instincts to believe that he will, when sick and ill, be content with the assurance that there is no use in his taking medicine, but that if he is quiet his disease will naturally pass away in process of time.

Almost as naturally as a dog when ill goes and eats dog-grass, so a man when ill feels that there must be something to be got at in nature which, though foreign to his usual habits of diet, will nevertheless be salutary for him in his time of distress; hence comes the art of drug-healing, which, as an art helped and supported by science, will be sought and required by all some time or other, so long as they are in the flesh.

During the last year the experiments of Dr. John Harley have added much to our knowledge of the action of conium, henbane, and belladonna.

With nicotine one case of tetanus has been fairly cured by Mr. R. Harrison, and Dr. E. Watson is able to report six cases of tetanus cured by the extract of the calabar bean, this bean appearing in its action to resemble nicotine, but to be safer and more manageable. If the patient is not able to swallow, then the tincture of the bean must be injected hypodermically, and a liniment made with the tincture should be rubbed down the spine.

As a sign of therapeutic progress, I may mention the care that is now taken in the administration of alcohol in disease. Only a few years ago at King's College Hospital, the consumption of brandy was something enormous, now many cases of uncomplicated pneumonia and febrile diseases are treated, and get well in a most satisfactory way, without the use of any stimulant at all.

In another year, thanks to Drs. Thudichum, Dupré, and Anstie, we are likely to have much added to our knowledge of the effect of alcohol on the system in health and disease.

I can, in concluding, merely name among the doings of the year the introduction of nitrous oxide gas as a useful anæsthetic in dental surgery; it appears now to have been used in several thousand cases, and without any accident. The first idea of this gas being of use as an anæsthetic we owe, as is pretty well known, to the bright genius of Sir Humphrey Davy.

There are other matters I wished to have mentioned did our time permit, among them Professor Haughton's Experiments on Food, Work, and Disease; also the excellent and interesting Gresham Lectures of the Past Year, by my friend, Dr. Symes Thompson.

I wished too to have said a few words respecting certain very carefully conducted experiments (as Dr. Carr can testify), on the action of mercury upon the liver, instituted by Dr. Hughes Bennett. For my own part I doubt how far we may legitimately infer the action of mercury on the liver of a bilious man from experiments made on a healthy dog; and it appears that the results of the experiments do not accord with the practical experience of most of us, which certainly tends to teach us that mercurials are what we call cholagogue, or bile-producing medicines.

From the matters I have brought before you, rather in a discursive than in a regularly systematic way, I think you will say that we doctors, in our constant warfare against disease, may rejoice and be glad when we look at the progress we have lately made in all branches of our art. We must still persevere and fight our battle against popular prejudice, ignorance, superstition, bad air, bad water, bad drainage, and all the diseases arising from these or any other causes. We must learn to practise treatment in the widest sense of the word. Sometimes all we have to do is to watch carefully our patients as they pass through those of the acute specific diseases which we know must run a definite course. In these cases our treatment consists in supporting the strength and watching against any sudden complication that may arise, such, for example, as the inflammation of any important organ, such as the lung or brain. In these cases—

> Est medici *curare*, auroque remunerat æger;
> *Sanare*, e cœlo, munere gratuito.

It is not always, however, that the sick man can remunerate the care of his physician with his gold, and we must all learn to regard it as one of the privileges of our order to be able to give priceless services to our sick fellow creatures without fee or reward.

Above all things we must remember that we are always students and learners, from the very time when we first enter at the hospital, even up to the solemn hour when we, passing from earth ourselves, learn what that event is in itself, to the aversion of which from our fellow men our lives and energies have been, as we would humbly trust usefully devoted.

Original Communications.

FURTHER EXPERIENCE IN THE TREATMENT OF PHTHISIS PULMONALIS, &c., BY PANCREATIC EMULSION.

By Richard J. Kinkead, A.B., Lic. Univ. Dublin, L.R.C.S.I., & L.M.D.

Perhaps the strongest tendency of the human mind is to generalize facts, to "carry up our knowledge into unity." Were it not for this faculty, the varied phenomena of the world would be unintelligible; their very number would confound us; and our finite intelligence would be incapable of comprehending their infinite variations. But this principle of our mind teaches us to assort them into classes, and so reduce them to the range of our capacities. This love of unity, whilst it, by making the incomprehensible comprehensible, opens wide a gate to knowledge, and guides to new discoveries, also leads the unwary into error. "Hardly is there a similarity detected between two or three facts than men hasten to extend it to all others," and thus a theory is formed; "and if perchance the similarity has been detected by ourselves, self-love closes our eyes to the contradictions which our theory may encounter from experience."

In no profession does this faculty of the mind lead to more glorious results or graver errors than in the medical. We have innumerable theories of disease—some true, others false; but no disease surpasses tuberculosis in the number and variety of its theories. Most of these having their foundation on one or two similar facts, all other points, even if at seeming variance, are explained on the system of the happy author of the theory.

But, fortunately, our treatment does not depend on the truth or falseness of these theories. Long observation has shown what remedy is likely to prove useful, what medicine will alleviate suffering. I do not intend in this paper to discuss the relative merits of any of the multitudinous phthisical theories, nor do I purpose to consider the treatment of pulmonary consumption in its entirety; but leaving out climate, regimen, hygeic regulations, &c., to restrict myself to what is its most important, but yet only partial treatment—the oleaginous.

That tuberculosis is a constitutional disease, and that tubercles are merely the effects, the products of this systemic affection, is demonstrated more clearly as our clinical and pathological researches become more extended and more accurate. The nearer we approach to a knowledge of the causes of the origin of the bad habit of body which produces tubercle, the more successful we will be in not only curing, but also in preventing this terrible malady. In fact, our only hope rests on our knowledge of it as a constitutional affection.

However divided on other points, physicians are unanimous in recommending fat, or rather oils, in tuberculosis. This shows the very general belief, that the quantity of fat contained in food is either not assimilated, or that a sufficiency is not digested to supply the necessary amount of respiratory food. The conviction that it is the fatty assimilation that is out of order is steadily gaining ground.

The intense dislike to fats generally manifested by tuberculous patients, frequently existing before any physical signs of disease can be detected, and the inability to retain them on the stomach when taken, indicate a deficiency of digestive power.

Two questions now naturally arise—

1st. What causes this deficiency of digestive power?

2nd. How does the non-assimilation of fat cause the production of tubercle?

I do not attempt the answer of the latter—it is still a debated subject; indeed many doubt whether tuberculosis is caused by oleaginous food not being assimilated. To anyone interested in this question I would recommend the study of Dr. Horace Dobell's little work on Tuberculosis, which contains the most rational hypothesis I have yet seen on the subject.

Since, then, the digestion of oleaginous food is incomplete, since it in some way causes the deposition of tubercle, and since physicians for the most part are agreed that the introduction of fatty matters into the system affords the best prospect of curing the disease, the great question for the practical physician is how this may best be effected.

"The efforts of the practitioner should be directed to the digestive rather than the pulmonary system, that the kind of morbid nutrition in the body generally, and altered morphological changes in the tissues of the organ where the deposit takes place, appear to be chiefly due to the excess of albuminous, and deficiency of fatty elements in the chyle. It has been now fully shown, especially by the observations of Dr. Bennett, in the first instance, confirmed by the extensive experience of the physicians of the Brompton Hospital for Consumption in London, that such treatment as is directed to remove the mal-assimilation of food frequently checks the tendency to the repeated occurrence of tubercles, while those that previously existed remain harmless; that general symptoms and physical signs may disappear completely; and that even extensive excavations in the pulmonary tissue may heal up and cicatrize." To improve the faulty nutrition, "it is of all things important that fatty matters should be assimilated in large quantities."[*]

Until a short time ago, cod liver was without doubt the best medicine we possessed, and that it is a most valuable one is, I think, an undoubted fact; far superior to other animal fats and oils which have been tried, such as cream, butter, neatsfoot oil, &c.; fat meats, as pork, mutton chops, bacon, &c. But when we try to administer cod liver oil we are met by a difficulty which it is often impossible to overcome, that is, to enable the patient to take it; for if we can overcome the distaste to fats of all kinds which usually exists, and induce our patient to try it, in most cases we find that the stomach will reject even very small quantities of the oil, and although in some cases it may at first be retained, yet, after a short time, it will be rejected. In many instances we can by no means overcome this intolerance of the stomach. That this is not due to the excessive acidity of the strumous dyspepsia, present in nearly all tuberculous patients, is, I think, proved by alkalies so signally failing to procure the retention of the oil.

If we examine, then, the effects of cod liver oil, we find in some it is retained, and acts most beneficially, even performing a cure. In some it is retained, and acts beneficially for a time, but then its good effects cease, and the patient gradually gets worse. In others it is retained for a short time, and then rejected before it does much good; and in others it is not retained at all. There are a few cases in which the disgust to oils is so great that even an attempt to take it cannot be made.

What is wanted, therefore, is a remedy which will aid the good effects of cod liver oil in those cases in which it is retained, and which will supply its place in those in which the oil is rejected, and (as in phthisis it is necessary to succeed in getting a large quantity of oleaginous food assimilated) will educate the stomach to retain cod liver oil and other fats. The agent that will, I believe, do this is pancreatic emulsion, the credit of introducing which belongs to Dr. Horace Dobell.

The emulsion has many advantages over cod liver oil. It will be retained where the oil has been rejected. This has been proved by experience. In patients of my own I have found it to be the case.

In 1867, Dr. Dobell published a "Report on the Experience of Medical Men who have used Pancreatic Emulsion of Fat." In collecting materials for this report, amongst others the following question was asked—"Have you found that patients can take the emulsion when they cannot take cod liver oil?" Thirty-two medical men sent answers to his queries; twenty-nine of these answered this question in the affirmative.

In a report of cases treated by Dr. Freke in Steeven's Hospital, the same testimony is borne:—"The emulsion and cod liver oil was tried in six other cases of pulmonary consumption under Dr. Freke's care, in all of which it produced a speedy and well-marked improvement in the digestive organs, and proved far superior to the oil alone. In no single instance did it disagree, and in several instances patients who were at first *quite unable to take cod liver oil, even in small doses*, found that a few drachms of pancreatic emulsion enabled them readily to do so."[*]

This report also bears very strong testimony to the truth of a statement that I made in a former paper on the subject, that "after the emulsion has been administered for some time it will be found that cod liver oil will agree in those cases in which before it did not."

(To be continued.)

◆

ON FISSURES OF THE ANUS, AND ULCERS AT THE LOWER EXTREMITY OF THE RECTUM.

By Holmes Coote, F.R.C.S.,

Surgeon to St. Bartholomew's Hospital.

The amount of pain which the presence of fissures of the anus or small ulcers at the lower extremity of the rectum may cause to the patient is often so great as to excite the surprise even of the surgeon. I may mention in illustration the case of a lady lately under my care, who, without knowing exactly the cause, assured me that she had been for the last eighteen months worn out by suffering, and was unfit for the performance of any domestic duty. The pain was not confined to the bowels, but extended to the loins, hips, and thighs. During the day she often felt as if "her legs would give under her," and at night time the rest was disturbed by cramps. More than all, she complained of sudden irritability of the bladder and urethra, rendering the desire at once to expel the urine almost uncontrollable, and this act was followed by a feeling of tenesmus, perhaps by a slight escape of fæcal matter, and by an access of pain in the region of the fissure.

---

[*] Aitkin, Practice of Medicine, vol. ii., page 280.

[*] Cases under care of Dr. Freke. Reported by S. Flood, M.B. Medical Press and Circular, October 7, 1868.

These pains are not fanciful nor exaggerated. I have had under my care strong and otherwise healthy men, and delicate women in all stations of life, and sooner or later with them all, the suffering caused by this apparently slight affection is such as to render them prostrate, and willing to undergo any operation for relief.

When the surgeon examines the patient, he may at first see but little to attract his attention: one of the folds of integument about the anus seems a little fuller than the rest; upon closer inspection the skin will be found red, excoriated, and superficially ulcerated, the parts, however, packed together so as to constitute a "fissure." It has none of the appearance of a "tuberculous" ulcer, and possibly the explanation usually given by the patient is the correct one, namely, that it came on by the act of straining in defæcation. Such patients are for the most part inclined to constipation of the bowels, and many, as is well known, show great neglect on matters of this sort, which are all-important to health.

It is fortunate for the patient that in these cases relief may be afforded promptly and completely. All that is needed is to throw the parts into a state of rest, when the pain disappears and cicatrisation is soon completed. The mere stretching of the ulcerated structure by the introduction of the finger, or of the small speculum into the anus, is often followed by immediate alleviation of all the symptoms. Indeed, Recamier recommends this method of treatment; he stretches the fissure until he lacerates it, and thus, perhaps, a state of the most perfect rest—muscular as well as otherwise—is temporarily produced. It has found favour with some of our own surgeons (vide Duigan, *Dublin Hospital Gazette*, Sept. 15, p. 277, 1860).

I prefer the division of the fissure by means of a straight knife introduced along the finger. The loss of blood is trifling, the pain momentary, and the relief at once complete. Indeed, the very aspect of the patient is changed when the surgeon revisits him.

The bowels had better be kept quiet by opium for a few days, and then relieved by mild aperients, such as sulphur and senna.

Nélaton and Trousseau recommend for the treatment of fissures of the anus, enemata of ext. krameriæ, gr. 75, to water, ℥iij., used morning and evening, and retained fifteen to twenty minutes, as long as there is pain on returning the injection. When the pain has ceased they may be used once a day, or once every two days. It is also useful to apply locally a magma of bismuth, one part to three of glycerine.

In cases where patients have declined the usual operations, I have obtained benefit from the use of carbolic acid.

Some extremely interesting cases illustrative of this affection have been described by Mr. Hilton, surgeon to Guy's Hospital ("On Rest and Pain"). In one case an anal ulcer produced retention of urine and symptoms of pregnancy. The patient, a young lady, aged twenty-two, withdrew from society, and passed her days lying on the sofa. In former times this would have been called "hysteria." By careful examination, however, the seat and nature of the disease was discovered, and complete relief given by the usual operation (p. 291, op. cit.). In another case an anal ulcer was accompanied by pain along the sciatic nerve, over the left hip and loin, with pain in the right leg (op. cit., p. 932). Arterial hæmorrhage has been cured by division of the ulcer. In a case under my care, that state of morbid irritability of the vagina, now called vaginismus, was kept up by a similar morbid condition, and was also relieved by the division of the ulcer.

These remarks do not apply to cases of extensive ulceration of the mucous membrane of the rectum, but to those conditions which have been well arranged under three heads: 1st, the crack or fissure of the anus; 2nd, a superficial ulcer, almost invariably co-existent with varicosity of the veins of the rectum; 3rd, an excavated ulcer situated between the external and internal sphincters (J. Prouse, *British Medical Journal*, 1860).

ON THE CHANGES PRODUCED BY DIRECT CHEMICAL ADDITION ON THE PHYSIOLOGICAL ACTION OF CERTAIN POISONS.*

By Drs. A. Crum Brown and Thomas R. Fraser.

In this paper the authors communicate the first results of an attempt to discover the relation which must exist between the chemical constitution and the physiological action of a substance. As the chemical constitution of the majority of physiologically active substances is unknown, they investigate the subject by examining the physiological action of a substance before and after the performance upon it of a definite chemical operation, introducing a known change in its constitution.

This comparison leads to a suspicion that physiological activity is in some way connected with *chemical condensation*, by which term the authors mean susceptibility of addition, whether the addition takes place by the increase of the atomicity of an atom, or of a group of atoms. This suspicion receives some confirmation from the fact, that such of the stable combinations of pentatomic arsenic and antimony as have been examined physiologically, are stated to be inert, while all the soluable compounds of triatomic arsenic and antimony are active; similarly, the aromatic bodies are, as a rule, more active than the corresponding fatty bodies.

The poisonous alkaloids thus examined, and included in this paper, are strychnia, brucia, thebaia, codeia, morphia, and nicotia. The authors give details of the processes followed in obtaining the iodide and the sulphate of the methyl-derivatives of these bases, and they describe their physiological effects.

Twelve grains of iodide of methyl-strychnium, subcutaneously administered, produced no effect on a rabbit, weighing three pounds. Fifteen grains were recovered from, after symptoms; and twenty grains was a fatal dose. When exhibited by the stomach, twenty grains of this compound did not cause any symptom; while the same rabbit was rapidly killed by one-tenth of a grain of strychnia, given in exactly the same way. Twenty grains of iodide of methyl-strychnium contain about fourteen grains of strychnia.

Both the iodide and the sulphate of methyl-strychnium produced symptoms altogether different from those of strychnia. There were no convulsions, nor was there the slightest exaggeration of the reflex function; the symptoms were those of paralysis, and death was produced by the asphyxia that this occasioned.

Brucia and thebaia act in the same way as strychnia, and it was found that iodide and sulphate of methyl-brucium and methyl-thebaium have the same action as the analogous strychnia compounds.

Recognizing the possible fallacies connected with experiments with such a substance on rabbits, the authors determined to observe the effect on man. One of themselves, accordingly, took, on one occasion, half a grain of

BY MR. MORGAN, F.R.C.S.I., &c.

iodide of methyl-morphium as a powder, and on another, one grain (containing about three-fourths of a grain of morphia), but on neither occasion was there observed the slightest soporific or other effect.

The authors have also investigated the action of iodide of methyl, and they obtained no evidence in support of the extremely improbable hypothesis, that some of the changes produced in the action of the substances they had examined might have been due to the addition of the physiological action of the methyl compounds. They conclude by discussing the possible causes of these modifications, by pointing out some of the practical applications of their results, and by promising to examine how far iodide of methyl may prove an antidote to the poisonous effects of these vegetable alkaloids, whose fatal dose it increases. In a recent paper "On the Physiological Action of Methyl and Ethyl Strychnia," MM. Jolyet and Cahours publish in *Comptes Rendus*, Nov. 2, 1868, results almost entirely corresponding with those of Crum Brown and Fraser, and announce them as their own discoveries, but have since yielded to them in priority as to the strychnia compounds.

Hospital Reports.

LOCK HOSPITAL.

ON THE OCCURRENCE OF CHRONIC GENITAL SORE OF A PECULIAR NATURE.

By Mr. Morgan, F.R.C.S.I., &c.,
Surgeon to the Westmoreland Lock Hospital, and to Mercer's Hospital, &c.

A form of chronic sore is of comparative frequency in the wards of the Lock Hospital. It bears no definite relation to the age of the patient, or even to the temperament; the robust, the young, and the debilitated presenting much the same appearances; although this form of sore no doubt appears more specially to affect those who have been for some time dissipated. The illustrations, which were taken as average examples of the affection, give a general idea of the local characteristics, which may be thus tabulated :—

1st.—They all have extreme density of the edge.

2nd.—They have great elevation of the edge, sometimes to even a quarter of an inch in height.

3rd.—They have a smooth, non-granular surface.

4th.—They secrete no pus, but a thin discharge.

5th.—They have a great extent of surface, often exceeding a crown piece in size.

6th.—They are extremely insensible, and difficult of irritation.

7th.—They are, my experience teaches, incapable of auto-inoculation.

The patients are not affected by inguinal enlargements, nor have suffered from buboes, although the sore has existed many months, the insensibility of surface being such that no inconvenience or pain was caused by intercommunication, and the extent of the sore was almost unperceived by the patient. As a rule there is evidence of a lurking syphilitic taint co-existing, but in no special form. I have seen gummata, papules, pains only, the birth of syphilitic children only, nodes and periostitis, as complications.

All the patients positively date the sore as commencing at a certain time and in the form as it exists for months. It is eminently not auto-inoculable, as I have repeatedly tried to procure auto-inoculation both before and after irritation, but without results.

After most careful inquiry I cannot ascertain that this sore has been communicated to others. In one case the same man cohabited with impunity for five months, the woman producing at the eighth month a syphilitic deadborn child. Though by no means certain, I am hardly inclined to think it communicable as such, for these patients generally continued their unhappy course of life for months before admission; in one instance, I am assured, for ten months continuously. I select the following cases as illustrating this form of sore. The woodcut shows the general aspect of the edges and surface, which are remarkable.

Case No. I.—*Chronic Sore of eleven months' duration.*

E. M., admitted April 1st, 1868 (Ward No. 6, Bed 6), æt. thirty-four, gives the following history. First unvirtuous fourteen years ago. Thirteen years since got a sore and suppurating buboes on both sides. Was subjected to full mercurial treatment at that period, and had no subsequent constitutional symptoms. Afterwards she married and lived with her husband eight years, but never was pregnant. Three years before admission her husband died, and she returned to her former life, and got a sore, which appeared in December, 1867. During the subsequent four months, till admission, she was living irregularly, pursuing an unvirtuous life. She states that the sore was but little painful, and secreted abundantly.

Coming under my care May 13, 1868, she presented the following evidences—is thin; looks much older than she states her age to be; has no pains, rash, or other constitutional signs. The internal organs are healthy; menstruation continues, but is irregular.

On examination, a large sore entirely occupying the orifice of the vagina was found, presenting all the appearances shewn in the illustration (Fig. 1), the edges being extremely dense, elevated, and welt-like, and of a whitish colour; the surface of the sore red, smooth, and secreting a scanty and thin pus; the sensibility very low, so much so that the patient had no idea of the extent of the ulcer. The inguinal glands were not enlarged. She was ordered large doses of iodide of potassium with bark, nutritive diet, and bisulphite of lime wash to the sore.

July 16.—She now got an attack of severe periostitic inflammation of the left tibia and ankle, which was resolved by blisters, fomentation, and rest, the iodide of potassium being increased in quantity per dose now to fifteen grains. She also had a periostitic attack of the sternum and clavicle, which was very resistant to treatment; and shortly afterwards suffered much from an ulceration of the upper gum, exposing the fang of the canine tooth. This healed, however, with rapidity, from local applications. As the genital sore remained obstinate notwithstanding local irritation and treatment, and as its appearance and conduct resembled much a lupoid ulceration, I determined upon the cautious administration of arsenic. I commenced with two-drop doses of Fowler's Solution, and afterwards gradually increased it to four, but the patient could not bear beyond this amount. In five or six days the sore showed slight indications of amendment. Being thus encouraged in the view I had taken, I now applied the solution five drops to the ounce as a lotion. The sore from this date gradually and steadily healed, and the general health improved. A gumma which formed on the thigh, and occasionally painted with R Iodinii, resolved itself, and the patient was discharged cured Nov. 26, 1868.

On Dec. 18, 1868, the patient was re-admitted, suffering from a gumma on the thigh, now ulcerating and painful. A sore has now formed at the posterior part of the vagina, in the cicatrix of the original. It has not the appearance characteristic of the chronic sore, but is more that of a rent from violence, and shortly afterwards healed.

On a review of this case, assuming the account to be true, which I believe it to be, we find no constitutional signs to have succeeded the first sore, and that the reception of a fresh poison dates altogether from the formation of this last as a primary, followed by well-marked constitutional manifestations—periostitis, gummata, ulcerated gum, and pains; the primary, though at first painful, soon took on the chronic character. I repeatedly used auto-inoculation, but invariably with unsuccess, equally whether the sore had been artificially stimulated or not.

From the serpiginous and chronic nature of the ulceration, its insensibility and chronicity, and its specially yielding to the influence of arsenic, I look on the ulcer as being in the first instance received as a specific sore, and becoming, under peculiar constitutional conditions, of a chronic or lupoid nature, but how far capable of contagion I hesitate to pronounce.

CASE No. II.—*Chronic Sore of six months' duration.*

No. 2 illustrates again this form of chronic sore occurring in a younger and more vigorous subject, accompanied by a well-marked papular eruption, and deafness from syphilitic myrengitis.

M. J. (Ward No. 2, Bed 7), admitted 10th March, 1868, æt. twenty-one, is stout, and apparently strong and vigorous; unvirtuous four years. Three years ago got a primary genital sore, which was treated without mercury. The inguinal glands of one side were enlarged, but did not suppurate. She remained free from any after consequences, pursuing an unvirtuous life till January, 1868, when she got a sore, small and painful at first, but gradually extending outwards on the nympha, and becoming insensible compared with its extent. After suffering with this for four or five weeks she came to the hospital; in addition having a well-marked papular eruption over the body generally, but specially developed about the back of the neck and shoulders. She was also deaf, and had some slight discharge from the ear, but was otherwise in robust health and good condition. The sore exceeded the size of a crown piece, and extended out on the nympha, presenting the hard, dense, cuticular edge shown in the illustration (No. 2). The surface was like red plush, devoid of granulations, but secreting tolerably freely. The characteristics of the sore in this patient were, however, not by any means so marked as in the preceding case, and there was more sensibility of the surface. I looked on the sore as being in that state bordering on chronicity, but not thoroughly established. I therefore treated it by local applications, stimulating lotions of sulphate of zinc, alternating with lotio nigra, repeated stimulation with nit. argeniti, nit. cupri, R iodinii, and carbolic acid. With some of these stimuli it was touched well every third day, the patient kept in bed, and treated by the internal administration of iodide of potassium, in gr. xv. doses, with bark.

Under the influence of this vigorous treatment the sore gradually yielded and healed, leaving the peculiar indentation always remaining as the site of the sore; the surface healing by a skinning process, and not by centripetal granulation.

She was discharged cured July 9th, 1868, having been upwards of six months a sufferer.

Reviewing this case, the local sore is found with papular eruption, syphilitic deafness, and preceded some three years previously by a primary treated without mercury. The characteristics of the sore, as will be seen by the illustration, were not so marked as in the preceding, and there was more sensibility of surface. I looked on this as being in that state bordering on chronicity; I therefore treated it principally by local stimuli, as before mentioned. Auto-inoculation always proved unsuccessful.

This patient has been lately again under treatment for ulcerated throat, but has no other symptom; the indentation corresponding to the original sore is well marked; her condition and general health is otherwise good.

CASE No. III.

Chronic Sore of fourteen months' duration.

F. R., aged twenty-six (Bed No. 5, Ward 1). Unvirtuous for seven years. Having been two years on the town, contracted a sore and bubo, for which she was treated in the hospital without mercury, and was discharged cured. She remained free from any symptom for a period of about two years, when she suffered from an extensive eruption, for which she was again admitted to hospital, submitted to mercurial treatment, and discharged cured. No further symptoms presented themselves till about July, 1867, when a sore formed at the side of the vaginal orifice, which gradually increased in size, yet without causing much pain. She was admitted to hospital in October, 1867, about three months subsequent to the first formation of this sore (during all which time she was pursuing her unfortunate course). She was now treated for three and a-half months, but though not cured, she left, and resumed her mode of life for eight weeks, when a papulo-squamous eruption having manifested itself, she again was admitted on March 3rd, 1868, and subjected to a mildly mercurial treatment by the exhibition of the compound calomel pill. Under this influence the eruption gradually yielded and the general health improved, but the sore remained.

In the first week of July, 1868, another crop of papular eruption appeared, some of the papules being isolated and some in clusters and annular. On the 27th of July the patient complained of lassitude and debility. On the next day a bulla had formed on the right thigh; during the next forty-eight hours another bulla on the left thigh; the next day another over the mons veneris. These bullæ were very tense and dark-coloured, filled with a sanguineous fluid, and surrounded by a blush or areola extending to three inches around, of a vivid red, shading off gradually. When broken, the cutis was found superficially ulcerated, leaving dark-coloured stains. A fourth and fifth bulla formed at succeeding periods on the shoulders, but were small, not exceeding the size of a fourpenny-piece, whereas the first nearly equalled a billiard ball in size. The bullæ were not interfered with, but simply kept covered and warm. Ten-grain doses of iodide of potassium and bitter infusion were given every six hours. Moderate stimulants and nutritious diet ordered. On examining the genital sore it presented all the characteristics shown in illustration (No. 3). The edges were cut out, greatly elevated and whitish, the surface devoid of granulation, red in colour, and almost insensible to pain. Having now lasted upwards of a year, during part of which time the patient was under the influence of mercury, which caused the disappearance of the eruption without inflaming the sore, I looked on this as a good case for testing the arsenical treatment. I therefore ordered three-drop doses of Fowler's Solution three times daily, and a lotion of Sol. Fowleri, ʒij.; R. opii, ʒij.; aqua ℥x. This application caused some irritation and stimulus to the ulcer, which gradually healed, the "welt-like" circumference disappearing, and the ulcer "skinning over." This is invariably the way that cicatrization takes place. There is no centripetal or healing process; long after the healing of the sore a well-marked cup-like depression and cicatricial margin is seen; and I have had one remarkable case under observation, where the cup-like depression left by this sore was to be seen nine years after the original affection. She was discharged cured. In this case the sore had merged into the true chronic or semilupoid condition, and required the full influence of the arsenical course to effect its cure. The extent of the ulcer was very great, and the margin as dense as cartilage. Auto-inoculation, though carefully performed, was unsuccessful, and the constitutional infection was evidenced by the presence of eruption. This woman was, while suffering from this sore, living irregularly, and if the sore were contagious, must have caused frightful mischief among the community.

The illustrations have been carefully taken of the exact size of the sores, and No. 3 shows well the irregular and welt-like edge which circumscribes the ulcer. There is another remarkable fact connected with their occurrence, that they affect mucous or mucoid surfaces. On another occasion I intend to illustrate cases of extensive ulcerations of the rectum, the entire urethral tract, and the mucoid surface of the vulva, lasting for over twelve months, and of extreme intractability; and I have had lately an opportu-

nity of examining after death a case where the entire urethra was taken away by this chronic ulceration, the opening of the bladder equalling a sixpence in circumference. No urine had been retained for months, the coats had thinned extremely. These cases furnish remarkable examples of the transition stages of the more chronic forms of this protean disease.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

The Society met on Friday evening, the 22nd of January, in the Albert Hall, Royal College of Surgeons, Professor Macnamara, Vice-President of the College, in the Chair.

Members present.—Messrs. C. Benson, Jameson, Wharton, Walsh, Elliott, Colles, Croly, sen., Croly, jun., Fleming, Jacob, Morgan, Murdock, Coulton, J. R. Kirkpatrick, Darby, Morrogh, Leech, W. D. Moore, Ferguson, H. Kennedy, Montgomery, Stoney, Roe, Stoker, Purcell, R. H. Moore, C. Moore, Willis, O'Grady, Grimshaw, J. Brady, Bookey, Kelly, D. White, Minchin, Swan, Wright, E. Hamilton, W. Stokes, jun., P. White, F. T. Porter, McSweeny, Croker, Butler, McClean, Skelton, J. K. Barton, Mapother, M. Ward.

CASE OF STONE IN THE BLADDER IN A BOY AGED SIX YEARS. LATERAL OPERATION—RECOVERY.

Mr. **Henry Gray Croly** said:—The case I am about to bring under the notice of the Society is one in which I performed the lateral operation of lithotomy; and as the operation is not one that is usually adopted in Dublin, I thought it would be interesting to lay the specimen before the Society, and hear the opinions of the members on this mode of operating.

M. G., aged six years, a handsome and extremely healthy-looking boy, was admitted under my care into the child's ward of the City of Dublin Hospital, in October, 1868.

History.—Three years previously his parents noticed that he had some difficulty in passing water, and pulled occasionally at the prepuce. He sometimes altered his position in bed when trying to pass water, and screamed from pain. The stream often stopped suddenly, and one day on which he suffered intense pain he passed a small calculus about the size and shape of a pea. The symptoms from that time disappeared, and the child enjoyed excellent health until April, 1868, when he again suffered from the same symptoms, which increased in severity. He was brought to me by his mother, and on hearing the history I placed the boy under the influence of chloroform, sounded him, and quickly detected the stone.

On his admission into hospital he was a perfect picture of health, and, except for the frequent micturition and startings in his sleep, he did not at first suffer much pain. For some days he fretted a good deal after his mother, but soon became accustomed to the ward and played about the yard with some convalescing children. A troublesome attack of diarrhœa (occasioned as I discovered by fruit and cakes injudiciously brought to him by his sister) obliged me to put off the operation for some days. His diet was nutritious, but unstimulating, and he got a tepid hip bath at night.

On the 9th of November I performed lithotomy. A small dose of castor oil was given to the patient the night previously to operation, and his rectum was emptied by an enema of warm water early in the morning. He was chloroformed in bed and carried to the theatre. The operation table was made of sufficient height (3½ feet) by firm pillows and folded blankets. The following instruments and appliances were arranged on a tray:—lithotomy jupe—a staff grooved on the side—long-handled scalpel, probe-pointed knife, forceps, blunt gorget—the tube with jupes and charpie—basin of warm water on floor for warming forceps and gorget—oil. The staff having been passed and the stone struck, the patient was firmly tied in the lithotomy position, and held steadily, with his buttocks projecting over the edge of the table. Before commencing, I introduced the forefinger of the left hand into the rectum to produce contraction of the bowel. Kneeling on one knee, and having fixed the integument of the perineum with fingers of left hand, I commenced the incision three-quarters of an inch in front of the anus and one line to the left of the raphè, and carried it downwards, backwards, and slightly outwards, well below the level of the anus and tuber ischii. This incision divided the integument fascia and fat. The second incision was commenced lower down, and having introduced the point of the forefinger of my left hand deeply into the wound, I quickly reached the shaft, and with the nail I pressed the membranous portion of the urethra into the groove, and divided the urethra, freely moving the knife from side to side to make sure of its being in the shaft. I next depressed my wrist, and elevated the point of the knife, keeping its point and back well up against the staff, and so passed it on into the bladder, the stop on the end of the staff telling me when it reached the bladder. Some urine now escaped. I laid down the knife and passed the left forefinger along the shaft into the bladder, the neck of which at this stage of the operation grasped my finger, and the stone fell against the finger's point. Standing up at this stage of the operation, the staff was withdrawn by Mr. Tufnell. I passed along my finger a small blunt gorget, and guided by it the forceps, which, acting as a sound, struck the stone. The gorget was withdrawn, the blades of forceps opened, the stone seized in long axis, and withdrawn with facility. Operation completed in two minutes and thirty seconds. I next passed in the tube, well oiled and plugged around with charpie. Canula was retained by means of tapes, legs and hands were loosed, and the child, who quickly recovered from the effects of the chloroform, was removed to bed, which was comfortably prepared with hot jar—mackintosh and cross sheet—knees tied together, and legs placed on a pillow.

12 noon (two hours after operation).—No hæmorrhage; urine passing through canula, but not very freely.

2 p.m.—Muslin of plug saturated with urine; not much urine passing through catheter; plug removed, as it seemed to act as a foreign body; urine then passed freely through incision.

5 p.m.—Patient was restless through the day, and complained of pain in incision; got an anodyne, which was rejected.

10th (day after operation).—Patient slept well; took ice, chicken broth, and milk; urine passing freely through incision; cross-sheet drawn regularly; pulse 130.

11th.—Slept well last night; skin cool; countenance cheerful; buttocks well dried and dusted with flour to prevent irritation from urine.

13th.—Wound commencing to granulate.

15th.—Small quantity of urine passed by urethra.

16th.—Urine passed by urethra.

18th.—Nearly all the urine passed by urethra.

Dec. 1st.—Patient allowed to get up.

Discharged perfectly well on the 6th of December—twenty-seven days.

The subject of lithotomy in early life is one of great interest to the surgeon, and the operation is one that requires considerable care. It is of great importance to remember the difference of position which the bladder presents in a child and in an adult. In this case, as I have already stated, I used a staff grooved on its side, and completed the operation with one knife, thus adopting the London mode of operating instead of using the second knife for the purpose of enlarging the neck of the bladder, as was generally adopted in Dublin. The chief danger in operating on a child appears to be the chance of the surgeon missing the bladder and getting into the recto-vesical space; secondly, not opening the urethra and neck of the bladder sufficiently with the knife, but pushing these parts before the finger and so tearing across the urethra, and thus necessarily being unable to complete the operation; and thirdly, running the knife too far along the groove of the shaft into the bladder, and thus wounding the posterior part of that organ. In this case I had the probe-pointed knife on the tray, and before commencing the operation I determined, if I found it necessary, to use the second knife; but I confess when I had got the knife into the groove of the staff and fixed it there, I thought it better to go into the bladder with that knife, especially as I knew from sounding that the stone was not a large one.

Mr. **Croly** then exhibited a section of the stone, which was chiefly composed of lithic acid with a nucleus of oxalate of lime. He expressed a wish to hear the opinions of the members on these points; first, as to the use of one knife; second, as to the use of a staff grooved on the side; and third, as to the use of a chemisette plug—whether it was of use in any case except where hæmorrhage was expected.

The **Chairman** observed that these cases possessed great interest. The questions submitted by Mr. Croly for discussion were well worthy of consideration—the employment of one knife only, the side-grooved staff, and the *canule à chemise.*

Mr. **Croker** said that about two years ago he operated for stone on a child eleven years of age, who had been sent up from the Curragh. He used but one knife, and the stone was one of considerable size. He used the side-grooved staff, and did not find the chemisette tube at all necessary.

Mr. **Fleming** observed that he had operated in a good many instances for stone, and had always used the lateral grooved staff, because he supposed he was accustomed to it. With respect to the knife, he had often employed a single knife, and more frequently he had used the lithotome with the knife. He must acknowledge that, in the case of children especially, he should be doubtful as to the safety of the single knife, except under particular circumstances. He should be apprehensive that without precaution a single knife might be sent further than was desirable. As to the *canule à chemise*, he had constantly used it. He had experienced in three or four instances the necessity of its early removal, as remarked by Mr. Croly, but that might possibly arise from their own fault. Surgeons were sometimes not sufficiently careful, when using the chemisette, to bear in mind the age of the individual. If too long a canula were used in the case of a child, they ran the risk of driving it in further than was desirable, and causing a portion of it to come into contact with the lining membrane of the bladder. In such instances he had seen the flow of urine prevented from coming through the canula, but he was favourable to its use generally speaking, and he would refer the Society to some remarks by the late Dr. O'Ferrall on the use of the chemisette after the operation for lithotomy. He did not mean to insinuate for a moment that in the hands of Mr. Croly the accident would occur to which he had alluded; but he certainly thought the lithotome was a safeguard to the operation, and an especially valuable assistant in the operation on a child.

The **Chairman** said he remembered an interesting lecture on lithotomy by Sir Philip Crampton, in 1847, in which he says that Mr. Dease, a celebrated surgeon in this city, latterly used but one knife only in operating for stone, and Sir Philip went on to pay a very high tribute indeed to the reputation of Mr. Dease, "the greatest surgeon," he called him, that this country had ever produced. So that what was originated some seventy or eighty years ago in Ireland was found worthy of imitation in London, and at last received the name of the London method of operating; whereas it was in reality the Irish method.

Mr. **White** said he had assisted the late Mr. Smyly on four occasions in operating for stone, and that gentleman only used one knife, and was always an advocate for that mode of operating. Mr. Smyly spoke to him on several occasions of its being a satisfactory method, and one to which the surgeon could easily train himself. He was rather surprised to hear Mr. Fleming speak so strongly in favour of the *canule à chemise*. The experience in the Meath Hospital was that it was unnecessary. He did not remember more than one case out of a considerable number of operations which he saw performed there, in which the canula was used, and in that case the reason for using it was that there was a tendency to hæmorrhage.

Mr. **Croly**, in reply, said, when he spoke of using one knife as a London mode of operation, he merely alluded to the general system adopted there, whilst he believed the majority of surgeons in Dublin used the second knife for the purpose of enlarging the neck of the bladder. As to the danger of using only one knife, he knew when he had got the knife as far as the stop, that he had got to the neck of the bladder, and he then used his finger. The chemisette plug which he used was a small female catheter suited for a child's urethra, and with a small piece of cambric upon it, so that it could not get further into the bladder than was necessary. He thought, however, when there was no danger of hæmorrhage, that bringing the child's legs together was better than using the canula.

Mr. **Morgan** detailed a case of

SUBCLAVIAN ANEURISM OF THE RIGHT SIDE,

and exhibited a preparation of the parts. The aneurism occupied the second and third stages of the artery, and partly engaged the first also; it was the size of a goose's egg, and had eroded the first rib, which formed a part of its wall; the brachial plexus was expanded over the tumour, and seemed to grow out of it, so intricate was the union; the branches were spread over the posterior part, the fascia over the artery, in its first stage, and the sac was very greatly condensed, thickened, and adherent; the internal jugular vein was very small, and both it and the pneumogastric nerve were also intimately adherent, and expanded over the vessel; the accompanying subclavian vein was also contracted, and adherent.

The artery itself was obliterated to one-third its ordinary size, hardly admitting a No. 4 catheter; the opening into the sac was of a curious triangular shape, owing to the adherence and compression of the thickened tissues around. The interior contained a good deal of laminated fibrine in parts, but not regularly deposited over the interior; some of this appeared of a recent date, judging from its density and adherence.

The left carotid arose close to the innominata arteria, lying in front of the trachea in its course upwards. The tumour had drawn over to itself the right carotid.

The collateral vessels were greatly enlarged. The aorta, when opened, showed a large deposit of ætheromatous and ossific deposit, the degeneration extending into the arteria innominata itself, which was affected irregularly over half its interior.

The heart was normal in size and condition. Several of the bronchial glands contained calcareous matter. The lungs were hypostatically congested to an excessive amount, and a quantity of bloody serum had been effused in the pleural cavities, especially on the right side.

The preparation showed the impossibility of exposing the artery itself, owing both to the adherence of the tissues around, and to the contracted and semi-obliterated state of the vessel, and the right carotid artery at its origin.

The history of the case was interesting, as showing the influence of position on the aneurism and on the parts in its vicinity.

Thomas McC——, aged thirty-five, of stout build, rather below average height, first came under Drs. Little and Barton's observation at the Adelaide Hospital on January 22, 1868. About *seven years* before, he was troubled with pains, and stiffness all through the arms and shoulders, which he attributed to working as a dyer. The pain, &c., in the left arm soon after abated, but increased in the right, his occupation being now chiefly cutting bread with a large knife in a union. He felt this very trying and fatiguing, and finally gave it up. Previous to this date, *nine months* ago, he felt a "kernel" above his collar-bone, which "went ticking like a watch"—that is, *twenty-one months* before the operation, he first noticed the tumour by its pulsation and size, and for seven years had suffered from pain. He states that he was never affected by syphilis in any form, has healthy children, and has always been a hard-working man.

On examination (22nd January, 1868), the tumour was about the size of a large hen's egg, pulsating visibly and centrifugally, extending from a level of cricoid cartilage to the clavicle and below it; there was a bruit over the tumour, and the hand and arm were somewhat numb; he could not discern a shilling when held between the finger and thumb; the pain was rather severe at times. On making an examination of the tumour at this date, it would appear that pulsation from the axillary downwards was suddenly arrested, as supposed, from the disengagement of a plug of coagulum, as in the "manipulation" method of treatment. This condition lasted till the 3rd of February, when pulsation again returned in the vessels of his arm, and continued till the 18th of February, a period of fifteen days, when again the stream was interrupted. During this period he had been taking ten-drop doses of digitalis tincture, and then three grains of acetate of lead every four hours. On the 24th he was put up in a constrained position, with his hand on the back of his head, as this stopped the pulsation. The transversalis humeri and other vessels were now enlarging considerably.

March 28.—Tumour solid; pulse disappeared; pulsation disappeared *nearly*, and from this to the 15th of April remained stationary. He went to see the Prince of Wales's entrance, took some drink, and got excited. From that day the tumour became more active; the pulse, in brachial, radial, and ulnar, however, did not return; the anastomosing vessels were enlarged. Up to this date the treatment had been carried out of keeping the arm in the peculiar position above alluded to, and so restraining the pulsation in the tumour; indeed, the patient preferred this position *as far as practicable*.

On the 28th of September he came under my care at Mercer's Hospital. He had the appearance of a man who had suffered much. He was spare, but not emaciated. His chief sufferance now was from paroxysms of pain. The pulse at the wrist and large vessels had totally disappeared; the tumour was pulsating softer above than below the clavicle; there was a slight bruit also over the clavicle, not below. The transversalis humeri and colli arteries have vastly enlarged, and could not only be felt, but also seen, passing over the tumour. The descending branch of the occipital could also be felt, and the circulation evidently was supplemented or represented by them. The temperature of both arms was the same. The affected arm was greatly atrophied; the fingers most markedly clubbed. The anæsthesia was well marked, the patient resembling it to as if his hand was dipped in, or coated with, glue.

The heart's sounds were normal, but quick; no bruit could be detected at the origin of the aorta, but a faint one in its course, and getting specially distinct towards the tumour. The pain he suffered was at times of very intense character, which he relieved by drawing the arm well into the side and turning on the side a little, and so, as it were, to relieve the pressure on the plexus of nerves. The pain was not located in any particular spot—sometimes along the arm, sometimes at the chest, and again at the shoulder, being of a lancinating and severe character. He was particularly sensitive to cold.

There was no throbbing of the carotids, or headache.

(*To be continued.*)

DUBLIN PATHOLOGICAL SOCIETY.

DOUBLE ANEURISM OF THE POPLITEAL ARTERY.

Dr. **Robert McDonnell** said he wished to bring before the Society rather an interesting pathological specimen which had come from Dr. Bookey, of the Shillelagh Infirmary. The patient had a pulsating tumour in the popliteal space. He was in the infirmary for a considerable time, and had undergone a partial cure from pressure in the femoral artery. The tumour had become solid and apparently reduced in size. At the upper part of the space there was a second pulsating tumour. He was very intolerant of pressure, and refused to bear it beyond a certain time. His stay in hospital was protracted, and he had an attack of dysentery which carried him off, and gave them the opportunity of acquiring that specimen. It presented one aneurism cured, and the other undergoing cure, both in the popliteal artery. They could see the tendons of the adductor magnus muscle and the artery going through it; and after coming through it, there was a large aneurismal dilatation. From the lower portion of the aneurism the artery descended; and immediately behind the knee-joint, and lying on the ligament of Winslow, was a second aneurism, exceedingly hard, and which had partially undergone cure. The vein was pressed entirely aside and displaced so that it lay between the artery and bone, and they could see the nerve, which lay over the tumour and was extended upon it, which accounted for the very severe pain which the man had in the popliteal space and the back of the knee. It was not a usual thing to have two aneurisms within so short a space of each other. It showed the tendency the artery had to become diseased. There was no other indication of aneurism presented by the patient; the aneurism was limited to this particular place.

OBSCURE CASE OF PLEURITIS AND EFFUSION.

Dr. **William Moore** said, the specimen he now exhibited was taken from the body of a man admitted to Sir Patrick Dunn's Hospital on the 11th December. The history he gave of his case was as follows:—He was a car driver, and was in the habit of drinking fifteen or sixteen glasses of whiskey in the day, besides a few pints of porter. He was a man of about fifteen stones weight. In the month of May he slept in a damp bed, and got pains in his chest, and cough, and rigors, which laid him up for a week or ten days. At the end of that time he resumed his occupation; but he found in jumping on a car or walking up a hill his respiration completely failed him, and he was obliged to give up his business as car driver. He spat blood twice, but in very small quantities—once in July and again in September. He got extremely weak, and decreased in weight to ten stones; he suffered from profuse night sweats, from great asthma, and from loss of appetite. He also complained that the great toe became painful, but after a time the pain left the toe and fastened upon the ankle-joint; he was not able to sit up or move through the wards. He complained particularly of the night sweats, which were most exhausting. On stripping him, the left clavicle was manifestly lower than the right. On taking a deep inspiration he could not move the left side as well as the right. On placing the hand over the left side vocal vibration was altogether lost; it was feeble over the right. The man was not aphonious, but his voice was of a very low subdued tone. On percussion he was found to be dull from the left clavicle in front down to the base of the left lung; and there was also dulness from the left scapular ridge behind to the base of the same lung. The left side was an inch smaller than the right. The opposite lung was normal as regards percussion and auscultation. The stethoscopic sounds over the left side were extremely feeble—indistinct respiration was audible over the base of the lung, sometimes accompanied by a small crepitus. The man made no complaint of pain; his pulse ranged between 90 and 100; he had a total loss of appetite. The pupils on both sides were equal; there was no deformity of vision, no ptosis; he did not complain of dysphagia, but he had dyspnœa, except when lying on his back, which was his invariable posture. All these symptoms would tally with chronic pleuritis. There was nothing in the history of the man which would point to tubercular disease, nor had he the aspect of it. He was a well-coloured man, but he had this great emaciation—wasting night sweats, asthma, cough, falling in of the left side, dullness on percussion, and all these symptoms, according to his own statement, dating from a particular day. The explanation arrived at was that he had pleurisy with effusion; that the dulness over the top of the chest was due to the pleuritic adhesion, that the fluid had disappeared after the lapse of some time, and that the side had fallen in. The cardiac sounds were perfectly healthy. There was no bruit or increased heart's action. There were cardiac sounds under the left clavicle, but that tallied with the consolidation of the lung caused by the pleuritic effusion. There was no superficial vinous radiation over the chest. The patient went on in this way for some time, neither better nor worse; but in the evening of the 16th he gulped up a small quantity of blood, turned in bed, and died.

On *post mortem* examination the right lung was found to be permeable to air, the left lung was consolidated and covered with a thick pleuritic capsule. So far the diagnosis was right. It was somewhat smaller than the other lung, which would explain the falling in of that side. But how explain the sudden death? When the lung was cut into they found a kind of chronic pneumonia, although there had been no special evidence of chronic pneumonia. This, however, would not explain the spitting up of blood and sudden death; but on further examination they came upon the secret of the whole matter. There was an aneurism of the descending portion of the thoracic aorta. The aneurism pressed on the left bronchus; it corresponded to the third and fourth dorsal vertebræ; it was out of the way of nervous and sympathetic pressure generally, and therefore they had not these additional adjuncts to guide them in their diagnosis. There was also much atheromatous disease of the artery. Aneurism of the aorta was not diagnosed. It might be said they should have suspected it from the difference in the respiration of lungs. This would be natural if they had had dysphagia or any other link in the chain; but where the pulmonary changes could be explained by pleuritic effusion, and when the history of the case tallied so remarkably with the accession of acute pulmonary disease, the most rational and explicable interpretation of the case was adopted. The cause of death was not the quantity of blood which he spat out. He believed that the recurrent pneumonia might have been the cause of death; whether the healthy blood came from the aneurism or from the healthy lung he could not undertake to say.

LITHOTOMY FOR EXTRACTION OF A FOREIGN BODY.

Mr. **Porter**, President of the Royal College of Surgeons of Ireland, said, the specimen he had the honour of laying before the Society was one possessing some features of interest. It was a foreign body that he had cut from the bladder of a patient of his in the Meath Hospital on the 3rd of January. He was a man twenty-five years of age, and about two years ago he suffered from organic stricture of the urethra. He had been treated by a medical man, but he had given him so much pain that he thought he could manage himself with less suffering. About fourteen months previously he constructed a bougie out of a piece of gutta percha, and with this he proceeded to dilate the stricture. On the first occasion he passed it fairly into the bladder and allowed it to remain ten or fifteen minutes; on attempting to withdraw it he found great difficulty, and a portion, three-quarters of an inch in length, broke off, and remained in his bladder. Shortly afterwards he began to suffer from symptoms of stone, and in May last was sent to Mr. Porter by his friend, Dr. Ridley, of Tullamore. Mr. Porter had him on the table to cut out the foreign body, but he became so frightened that he insisted on leaving the hospital. A fortnight ago he changed his mind, and came back to be operated upon, and then he performed median lithotomy. He exhibited the portion of bougie, and remarked how beautifully the phosphatic deposit had been laid down in layers around it. It was very soft, and broke up under the forceps; yet he was enabled to extract a large portion of it attached to the bougie; the fragments weighed 140 grains.

THE VIRTUES OF DRUGS.

SIR THOMAS WATSON's farewell address to the Clinical Society of London contains some remarks which we feel disposed to take for a text in the following brief reflections on the virtues of drugs. All who have read the charming and graphic work of the learned and venerable President of the Clinical Society will, we are sure, acquit him from the charge which seems to have been made against him recently of undervaluing the powers of drug therapeutics. He says, indeed, that it seems to have been thought in some quarters that he had renounced his faith in physic; but he adds, and we are sure with great truth, that such a notion is the reverse of the fact. He is anxious only to have the effect of remedies carefully ascertained and certified, just because he has so much faith in them. What he deprecates, and would fain see altered, is the vagueness of aim, the uncertainty of result, and the merely tentative nature of too many of our prescriptions. He would, like Mr. Disraeli, like to have the precision of the modern rifle, which that politician hoped his followers possessed, instead of the hit and miss weapons of ancient warfare, against disease. In all these sentiments we thoroughly concur. There is nothing to our minds sadder than to contemplate the ruins of our old medical and speculative theories. Nothing more disheartening to the benevolent and to the searchers after truth—a small but gallant band at all times—than the sight of the conflicting systems which reign at the present moment in the sciences of medicine and of morality. Pilate, a philosophical magistrate of old, asks "What is truth?" and we here find a venerable and most distinguished President of our College of Physicians in 1869 asking "What is truth in medical therapeutics?" And this reflection is the more bitter to us, because we find in other sciences, such as astronomy or mathematics, but little if any of these uncertainties which surround us on all sides in investigating the cure of disease and the science of social life. Who would venture to set up an astrologer's observatory now-a-days for the foretelling of destinies? Who is there among us who, since the days of Lavoisier, Priestley, &c., has set up for an alchymist? Is there any quack navigator? No. All these sciences are now cultivated only by persons in whose scientific acumen no one doubts, and the results of their studies are readily accepted by us all.

M. Auguste Comte asserts, with much truth, that all sciences seem to go through a kind of measles, or teething period. The theological and metaphysical periods of astronomy and of chemistry are matters of history. Even arithmetic had its epoch of golden numbers, lucky and unlucky figures. Days and hours have had their superstitions attached to them. Friday has long been an unlucky day, &c., &c. But, whilst these sciences have got over *their* trials, we doctors seem but in the midst of *ours.* Homœopathy, hydropathy, kinesopathy, the imposition of pious hands, still dispute the whole ground of therapeutics with the ordinary practice by drugs; and it would appear that scepticism is so great in some quarters that it even infects the very high-priests of the art—the physicians in our hospitals. Our only remedy for this state of matters, we must confess, is to be sought in open and fearless discussion. Truth is best advanced by struggling openly with error, and we should like to see the homœopathists and others get a hearing, and be confronted with some of our ablest men, such as Wilks, Gibson, &c., when we doubt so little in the power of truth that we believe homœopathy might soon be proved to be a mistake, or, at any rate, the small dose system. But, as it is at present, our drug-keeping brethren, like the silversmiths of Diana of Ephesus, will not let the goddess be assailed; and hence scepticism darkly prevails, because it is the nature of all belief not to be worth much unless it is able to stand a fair fight against all comers. Have we not a parallel of this calamity in the disruptive process which is taking place within our Church establishments? The terrified priesthood and laity will not hear of open discussion, and the consequence is silent revolution.

Whilst we go along with the remarks of Sir Thomas Watson so far, we are *toto cœlo* at variance with him in his reasons for believing that drugs exist fit to alleviate human ills. He informs us that he is one of those who adhere to the doctrine of *final causes,* and that he believes that those subtle essences which human research and ingenuity have succeeded in deriving from various substances in Nature, and which, when applied to the human body, have such a marvellous power to abolish pain, to compel sleep, to extinguish fevers, and to stop for long—perhaps for ever—the paroxysms of epilepsy which have continued for years, were implanted in those substances by the Creator, among other uses, it may be, for those very services to mankind. Such doctrines, we confess, emanating from the "head of the profession in England," fill us with amazement and consternation. Here is M. Comte's theological period still illustrated by Sir T. Watson. What should we think of a chemist who should gravely inform us that he believed that it was a providential arrangement for our benefit that eight parts of oxygen gas combined with one of hydrogen to form water? or of an astronomer who should consider that the obliquity of the ecliptic was designed especially to make us comfortable? Are not such theories but empty dreams, foreign to the ideas of a positive science, such as we hope to see medicine become? Would not Sir Thomas Watson say that the method for investigating all sciences ought to be the same, and that our business is to find out in medicine, as in social science, and as in chemistry, what is useful and what hurtful to our race? If Nature were so kind to us, why so many catastrophes? She is, as some of our body lately said, often a step-mother, not a mother to us; and our task ought ceaselessly to be to escape from the evils which are constantly assailing us, not to live in a fool's paradise of final causes. "*Nullum numen abest, si sit prudentia,*" said the ancients. Drugs, like other things, have their good sides and their bad one. Let scepticism and discussion assail each one and all of them, and then, out of doubt, we may at length arrive at certainty; and finally, perhaps, medicine may arrive at the proud position now held by astronomy and chemistry, and cease to be a field for theological dreaming.

◆

SCOTLAND.

EDINBURGH.

SOCIETY FOR RELIEVING PERSONS WITH INCURABLE DISEASE.

The report read at the annual meeting of this institution showed that the state of the funds was on the whole satisfactory, and that the number of pensioners, ordinary and extraordinary, was 201, no higher number having hitherto been reported. For a long course of years the late Dr. J. R. Sibbald took a deep interest in this society, and left the residue of his estate to be applied to the objects contemplated by it. His trustees have not yet ascertained the amount, but it is expected to be considerable, and will either take the shape of pensions, or be devoted to the support of incurable patients in an infirmary or hospital. Be it which it may, the directors anticipate much pleasure in its application.

NIGHT ASYLUM FOR THE HOUSELESS.

Our Scotch friends seem to have an equally effective, and at the same time a more economical method of conducting their charities than we on this side the Tweed. We very much question whether a society affording the same amount of relief would not in England have required a far larger amount of money than we find expended in support of this Asylum. During the past year, 7,946 applicants have been admitted, or nearly twenty-two per night. For these, 18,349 meals have been provided, consisting of breakfasts, dinners and suppers, and the outlay by which all this has been accomplished was no more than £287 8s. 4d. Surely something may be learned in the way of administrative benevolence by the study of statistics such as these.

The death of Professor Strangeways, of the Edinburgh Veterinary College, took place at his residence, Links, on Saturday week. He commenced life as a bookseller, but afterwards became an apothecary, and subsequently began practice as a veterinary surgeon. He was appointed Lecturer on Veterinary Anatomy and Pathology, on the Chair becoming vacant at the College in Clyde street, and was very popular with the students. His illness was short, and he died at about the age of forty.

INFIRMARY SITE.

We understand (says the *Scotsman*) that the committee, after weighing all the evidence which has been laid before them, have come to the resolution of recommending the subscribers not to accept the new site at Watson's Hospital grounds. Instead, they are prepared to recommend that one of Mr. Bryce's plans, either No. 2 or No. 3, should be adopted, and that the buildings on the South Bridge should not be taken down.

Dr. Andrew Wood stated, at the annual dinner of the Edinburgh University Conservative Club, that in the Universities of Edinburgh and St. Andrew's, Mr. Swinton's election was frustrated by the votes of the medical constituency. It appeared from the list that the numbers were all against him. Mr. Campbell Swinton said he endorsed from his own knowledge what had been stated by Dr. Wood, that it was entirely by the members of a single profession that he did not stand in the position of a successful candidate.

ST. ANDREW'S.

The course of lectures given in the Town-hall, St. Andrew's, during the winter months, in connection with the Young Men's Literary Society, was brought to a close on Friday night, Professor O. H. Bell, M.D., having delivered a very interesting lecture on "Our Sanitary Responsibilities and how to meet them." The course has been on the whole successful.

ABERDEEN.

We understand that among the candidates for the Professorship of Midwifery in this University are Dr. Andrew Inglis, M.D., an extra-academical lecturer on this subject in Edinburgh, and Dr. Charles Bell, of Edinburgh.

STIRLING.

Lately, at this place, a District Lunatic Asylum was opened for the use of the counties of Stirling, Linlithgow, Dumbarton, and Clackmannan. The institution was examined a short time before the patients were removed into it by Sir John D. Wauchope and Sir James Cox, accompanied by Dr. Brown, of the Board of Lunacy, who expressed themselves satisfied in every respect with the arrangements.

KIRKCALDY.

It seems to have been the unanimous opinion of the meeting held to consider the subject, at Abbotshall, that a complete system of drainage was absolutely necessary for Linktown and Kirkcaldy, now that the Lothrie water was about to be brought in. Unless this were done it was considered that the sanitary condition of the town would be worse than before. All proprietors of houses were advised to put the water into their houses, as a pipe might be laid on to the main and there would be no need for cisterns.

◆

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, January, 1869.

ARSENIC AS A CURE FOR CONSUMPTION.—THE MORTALITY OF HOSPITALS.—CORRECTING [illegible]HE PRESS.

I[illegible] previous letter I had the pleasure of calling your a[illegible]ntion to M. Moutard-Martin's revival of arsenic as a remedy for phthisis. Having heard much more about it lately, I have referred to the mémoire read at the Academy, and propose to give your readers briefly the conclusions maintained by Moutard-Martin. He declares that arsenic has a very marked effect on pulmonary phthisis; that its action is much more efficacious in chronic cases than in those in which the progress is more rapid, or is accompanied by fever; in fact, he admits that in these latter his remedy is useless. In the great majority of cases the general condition of the patient is improved by the administration of arsenic, and that, too, in cases where there is hectic, and where the disease is far advanced. This improvement precedes the local beneficial effect of the drug. Further, he thinks the remedy has actually cured a number of the cases, and that these successful results would be more numerous if patients did not imagine themselves cured before they are, and so neglect to persevere with the remedy. To be of most use, *small doses* should be employed and continued over a long period. It is never necessary to give the doses recommended by some practitioners; and the author thinks it is never needful to go beyond two centigrammes a day. The dose may begin with fifteen milligrammes, and the tolerance varies much with different individuals. It should be only gradually increased. The earlier the stage the greater the tolerance of the remedy, though on this point M. Moutard-Martin seems opposed to most others.

The first action of the remedy is believed by the author to be of an alterative kind, and upon the pulmonary lesion; at the same time it possesses a direct action on the respiratory function, and may influence the pulmonary tissue itself as well as tubercle.

The above, I think, is a fair *resumé* of the views of the clever physician of the Beaujon, and of those who accept them. While so much attention is being given to consumption in England, your readers will, I hope, be glad to have so definite a statement of the therapeutical mode so carefully elucidated, and which has, to a certain degree, the approbation of the Academy.

The question of mortality in hospitals is again in the ascendant, *apropos* of some statements made lately by Sir J. Simpson, and repeated here by some with wonder, by others with satisfaction. One paper now before me takes it for granted that some are ready, on the strength of Sir J. Simpson's statistics, to abolish all hospitals, as palaces fitted for the propagation of epidemics and death. Another paper simply declares that statistics prove that in any hospital the mortality is one in 30 against one in 212 for operations of a similar kind in the cottages of the peasant, and proposes that everywhere little iron cottages should be used for serious cases. On the other hand, there are plenty of people who perceive at a glance how idle is the comparison of 1,000 hospital amputations with the same number performed by country practitioners in small towns, villages, and hamlets. There are so many things which render it impossible to make a ust selection of cases for comparison, and so many circumstances that contribute to the welfare of the country patient, that the whole argument is regarded as useless.

Figures will prove anything, say some; and if your Simpson will publish his statistics in full, we will undertake to prove that his conclusions should have been the reverse. I am not fond of statistical investigation myself, and can readily understand how people in France can thus speak. French budgets are a fine education, so far as teaching us to distrust figures. There is one point that all Paris physicians would agree upon,—viz., that the Lariboisière, so far from being a fair model, is a very defective hospital, and ought not to be taken as a standard. Its ventilation is very indifferent, and many of its arrangements far behind the general run of our hospitals. It ought, therefore, by no means to be selected as a specimen, and to put it forward is as unjust as to make out that every hospital staff crowds all its cases of large surgical wounds together. That practice does not obtain here. We are quite alive to the welfare of our patients, and believe that Paris may be compared with any city. That we are also *au courant* with the subject of hospital mortality, and ready to consider everything impartially, is seen in the fact that a report on the relative salubrity of La Charité and the Hôtel Dieu has been presented to the Academy, in which the latter historical and glorious hospital is unequivocally condemned. So great is the effect of this, that it would seem possible that the Hôtel Dieu will be shortly closed, that is, as soon as arrangements can be made. If, therefore, those who agree with Simpson illustrate their arguments from hospitals in Paris, let them abandon Lariboisière and not substitute for it the Hôtel Dieu; they are hereby notified that it would seem more honest to make their calculations from the statistics of La Charité, though they would do better, perhaps, to stick to their own hospitals in Great Britain—surely quite numerous enough for the purpose, and on which their mistakes would be more rapidly corrected.

I deem it superfluous to enter into the question of maternity hospitals. I thought everyone now knew their dangers, and that they were only a kind of *dernier ressort*, and yet could not be dispensed with without greater calamities than, as now conducted, they produce.

One expects press errors occasionally, but wishes to do credit to "readers for the press." I thank your "reader" for the care he bestowed on my former letters, and lest anyone detects some oversight in this, plead an excuse by relating that the Society of Printers' Readers here has written to the Perpetual Secretary of the Academy to point out some anomalies in spelling French which deserve attention, as they make revision excessively difficult. Who can be expected to remember which of the words *assonance*, *consonnance*, *dissonance*, and *résonnance* are written with a single *n*, and which with the double letter? Why should *fève* take a grave accent, and *sève* an acute one? Why should *sangloter* be written with one *t*, and *ballotter* with two? Why is a double *f* employed in the word *souffler*, and a single letter in *boursoufler*? M. Villemain, as Secretary, has replied by promising to submit the communication to the committee on the Dictionary.

Would not the English printers' reader be glad to see a dictionary by authority to which to appeal?

◆

Notes on Current Topics.

Pruning the Medical Department of the Army.

The authoritative announcement that no competitive examinations for admission of assistant surgeons for at least a year, has been quickly followed by sweeping retrenchment at Netley. The twenty-one past candidates—whose names we publish in another part of our issue as having completed their probation—have been dismissed to their homes, not with the definite two months' leave usually accorded to the candidate for his preparations for a commission, but with an indefinite dismissal "till further notice." Whether these gentlemen will be gazetted at the usual period, or whether they will be called into service at all, they are not informed.

The four assistant professors at Netley have also had unpleasant experience of the retrenchment policy. The understanding under which these gentlemen had all along acted, was that they should serve five years without any salary extra to their regular full pay as surgeons, and that at the expiration of the five years they should receive £100 a year. Two of them had served the whole term, and last year entered on the enjoyment of the promised salary the others were far advanced towards their service, and now the entire staff have been summarily ejected, and placed on the roll for appointment to regiments.

It is quite evident that this determination of the Government not to carry out the contract entered into with their medical servants amounts practically to breach of faith. No doubt the theory of the service is, that those who enter it are liable to half-pay at any time, but as a matter of fact the present wholesale reduction is unprecedented, and the medical officers could not, when they bargained with the War Office for certain services and certain payment, by any forethought have anticipated the failure in the Government to keep their promises. That such a consummation is possible at all must necessarily depreciate the service, for it will take from it the guarantee of permanency, which was its highest recommendation.

The Navy Curtailment Commission.

The members of the Commission appointed by the First Lord of the Admiralty to inspect and report upon the naval hospitals at Chatham and the other ports, consisting of Dr. C. Murchison, F.R.S., Mr. R. Ellis, and Mr. J. Holmes, paid an official visit to Melville Royal Naval Hospital, Chatham, last Saturday, and spent some time in the inspection of that establishment, over which they were conducted by Deputy-Inspector-General C. A. Anderson, M.D., and the other heads of the department. The object of the inquiry by the Commission is chiefly for the purpose of ascertaining if any and what reductions can be made in the number of medical officers and other officials at each of the naval hospitals, with a view of introducing a greater saving and economy in the working of each establishment. The result of the inquiry is to be reported to the Admiralty forthwith.

Public Health.

The following particulars, selected from the Returns of the Registrar-General for the week ending 6th February, may interest some of our readers. The deaths in London approached closely the estimated number, though less by 106 than the number recorded in the preceding week. The deaths from scarlet fever continue to decline, being in the last three weeks respectively 64, 53, 45, yet the disease, as shown by certain cases, still prevails with great severity. Fever patients are very frequently removed to the hospitals in ordinary street cabs, and the remarks of the Registrar on this practice are worthy of notice. He says, "The deaths from fever and other zymotic diseases would be considerably diminished if public vehicles were not used to convey infected persons; under the present system they become the means of propagating disease among persons who would otherwise escape the malady."

In the first five weeks of this year twenty-one deaths by violence in the streets of London were registered; that is, five persons were killed by horses, one by a carriage, two by omnibuses, two by cabs, five by waggons or vans, and six by carts. Every one must have noticed the danger to pedestrians from this cause in crossing the streets; we have ourselves been within an ace of being run over, not through want of care on our part, but solely in consequence of the unaccountable stupidity or fickleness of the driver. As the Registrar remarks again, "What appears the work of chance is the natural effect of causes which admit of control." The amount of water supplied by the London water companies for the month of January last was a *ton* by weight to each house, or 28·9 gallons to each person.

Phenic Acid as a Febrifuge.

At a recent meeting of the Academy of Sciences of Paris M. Clerseul communicated on the part of M. Calvert a note on the employment of phenic acid as a febrifuge superior to quinine. In the little town of the Island of Maurice, during the months of December, 1867, and January, 1868, in a population of 900 inhabitants 300 suffered from typhoid fever, and 41 died. Phenic acid was employed to disinfect the sewers and cesspools in the town, and for sprinkling with a weak solution the alleys and passages. The fever disappeared rapidly, and three months afterwards, in the report of Dr. Gower, it was established that from the 17th of February, when the use of the phenic acid was established, to the 1st of April only two deaths took place, both of them in the first fortnight.

Dr. Tessier universally treats his cases in the island by the same means, and with wonderful success. For example :—

> "After the administration, from June 7th, to a Creole attacked with intermittent fever, for seven days, of doses of quinine, the fever was arrested, but reappeared on July 1st, and, despite the repetition of the treatment, with the addition of salts of iron and extract of cassia, no good result was obtained.
>
> "Dr. Tessier then injected under the skin three-quarters of a grain of pure acid, dissolved in twenty drops of water, and the fever disappeared. A second injection was, as a precaution, made on the 12th, and the fever never returned. Twenty-seven patients submitted to the same treatment obtained the same happy result."

Drs. Barraut and Tessier consider that these results demonstrate that intermittent fevers are due to the presence of microscopic ferments, animal or vegetable, in the blood.—*Union Médicale.*

Prolonged Anuria.

Cases of suppression of the urinary secretion, as in cholera, persisting for weeks and months, are not frequent, and their rarity equals their gravity.

A woman of twenty-seven years of age, married but childless, after five months' suffering from amenorrhœa and leucorrhœa, consulted Dr. Gallina, because she had not passed urine for twenty-four hours. Catheterism only yielded a few drops of coffee-coloured liquid, and for the succeeding eight days no more of it appeared. Applications of leeches to the perineum, nitrate of urea internally, and warm baths were administered up to the twenty-fifth day. No effect having been produced, the patient consulted Dr. Albertini, at the Milan Hospital, who after two hours' minute examination, found absolutely no lesion to explain this failure of secretion, nor any alteration resulting from it. Her general health had suffered in no respect. Professor Rodolph being called into consultation, considered that the suppression was due to amenorrhœa. Emmenagogues were administered, and the menses appeared. At the same time 600 grammes of urine were extracted by catheterism on the 43rd day, and the normal secretion became established without the least injury to health.—*Gazette Médicale de Lombardia.*

Medical Relief in Paris.

A DOCUMENT of much interest has been published by M. Husson, Director-General of "L'Assistance Publique," from which we extract the following:—

In 1867, 277,342 persons participated in the public benefits of the department in the following proportions—

Hospital patients	96,704
Aged persons in infirmaries	9,023
Insane at Bicêtre and Salpêtrière ...	3,441
Paupers assisted by the "Bureaux de Bienfaisance"	105,119
Patients treated at home	38,173
Children in the country districts ...	24,880
	277,342

Nineteen hospitals (eight general and eleven special) and five infirmaries, four asylums, and three endowed infirmaries receive this number of persons.

The children are entrusted to nurses, who rear them in the country. In the thirteen provinces of the empire, twenty-three sub-inspection districts are maintained for the *surveillance* of the nurses.

Nearly 2,000 persons compose the medical staff of the "Assistance Publique":—

Physicians of Hospitals	78
Surgeons of ditto	15
Medical officers of the "Central Bureau"...	23
Prosectors	2
Apothecaries	17
Intern pupils in medicine...	137
Ditto in pharmacy...	97
Students in progress of education ...	481
Midwives and assistants	7
Medical officers for externs	203
Midwives for ditto	111
Medical officers for children in the country	245
Ditto for direction of nurses	60
	1,989

4,349 persons compose the administrative department, which gives a total of 6,338 engaged under various titles in the carrying out of the system.

Experiments on Coughing.

DR. NOTHNAGEL has sought by various experiments on cats and dogs to determine the exact points of the respiratory apparatus the direct mechanical excitation of which provokes cough. The irritation of the mucous membrane above the true vocal chords, or on their upper surface, gives a negative result, while violent coughing follows the excitation of the mucous membrane situated below them or in their interval.

The sensibility of the trachea is less, and diminishes rapidly. The cough is less energetic and less immediate, but the centre of the tracheal bifurcation is endowed with a sensibility as acute as the larynx itself.

The same experiments were repeated after section of the superior laryngeal and vagus nerves, and in this case the excitation of the bifurcation of the trachea and the larynx remain without effect if the superior laryngeal nerves only have been divided. The larynx is insensible, but excitation of the trachea produces coughing. The excitation of the bronchial mucous membrane laid bare by an opening in the thoracic wall provokes coughing, but with less energy than laryngeal or tracheal irritation.

The pulmonary parenchyma appears to be insensible. Cough is included amongst the symptoms of pleuritis, and yet direct irritation or even inflammation provoked in the pleural surface is not followed by coughing.

Irritation of the nervous trunks, which, after section of the nerve, were left intact, or of their central extremity, in no case caused coughing, and this result is accordant with the physiological fact that reflex phenomena respond more easily to excitement of the nervous extremities than to that of the trunks themselves.—*Virchow's Archiv.*

LIST of the candidates of Her Majesty's British Medical Service who were successful at the Competitive Examinations at Chelsea in August, 1868, and at Netley, in February, 1869, after having passed through a course at the Army Medical School:—

Order of Merit.	Names.	Studied at	Number of Marks.
1	Chatterton, J.	Queen's College, Cork.	5465
2	Stokes, A. H.	Dublin.	4863

Sir D. J. Corrigan's Parliamentary Candidature.

THE Liberal party in Dublin has already declared itself for the coming election contest, and has, at a meeting last week, adopted Sir D. J. Corrigan as their recognized candidate. The political supporters of the learned Baronet are strong in hope that the impossibility of offering persuasive arguments to the freemen, or of bringing up the outvoters (on proof of which proceedings the late Conservative member lost his seat), will make certain the return of their candidate. The Conservative party, on the other hand, are sanguine of retaining their political superiority, and have already declared that a candidate in their interest will be forthcoming at the proper time, and will be put in without a shilling of personal expense. It is already known that Sir Dominic Corrigan can calculate at no great support from the profession, for it is highly improbable that any proportion of the two hundred and sixteen medical men who voted against him will alter their course now.

The profession has been placed in a very unpleasant dilemma by Sir Dominic Corrigan's candidature, and the very extreme opinions with which he identified himself. Feeling, we earnestly believe, very strongly on the justice and benefit of Medical Representation in Parliament, and recognizing generally in Sir Dominic Corrigan a representative most eligible (apart from his political bias) for the advocacy of medical interests, they have, nevertheless, been compelled to occupy a position of antagonism, both to their profession and to Sir Domnic Corrigan.

The 216 medical supporters of the Conservative candidate—and we say so apart from political considerations—deserve credit for having deliberately sacrificed their personal feelings and their very obvious personal interest in deference to the great constitutional principles which they entertained; and we are convinced that had their political sentiments and their professional *esprit de corps* been in accord they would have supported Sir Dominic Corrigan both with voice and pocket.

The Vaccination Act in England.

A MOST vexatious exercise of the powers of the Vaccination Act was made public last week in Scarborough, and has created much excitement in that neighbourhood. Four gentlemen, Dr. Cooke, the Rev. Mr. Parr, and others, were summoned for neglecting to comply with the obligations of the Act. Dr. Cooke pleaded that the child had been in delicate health ever since its birth, and he had sent several certificates to that effect to the Registrar, and was perfectly ready to comply with the law as soon as the child's health was so far restored that he might do so without danger to its life. If Dr. Cooke had employed another medical man to furnish these certificates he would have been indemnified from all blame, but as he sent them himself, the evidence of the accused could not be taken, and he was condemned and fined. We understand that he has appealed against the decision.

It is quite obvious that the Legislature, in requiring the certificate of a medical man, in cases of unfitness to receive the vaccine virus, never contemplated the exclusion of such certificates because the first certified referred to the medical man's own child, and if the decision of the magistrates be law, it is obviously neither sense nor justice.

The Rev. Mr. Parr, it appeared, was also compelled to postpone vaccination in consequence of the weakly condition of the child, and actually did have it vaccinated as soon as possible, but the operation was unsuccessful.

Nothing can be more injudicious than the overstraining of the provisions of an Act made for the government of careless and unwilling persons, against gentlemen who had evinced their anxious desire to comply with its provisions, and by persistence in such a course a most valuable measure will without doubt be brought into disrepute.

The Presidency of the Medical Council.

THE rumours respecting this position, which we have duly chronicled in our columns, have called forth somewhat unexpected manifestations of opinion. Dr. Burrows has himself publicly protested against "the manner in which this important subject is being conducted," and intimated that if he retire it will be because he is "satisfied that the General Medical Council is prepared to elect a new President." It would almost appear that Dr. Burrows would not be unwilling to continue in the arduous position of President for some time longer; and we are really not surprised that the manner in which the possible duty of electing a successor is anticipated should prove disagreeable to many. There are members of the Council, besides Dr. Burrows, who think that certain proceedings of certain people deserve only condemnation. But the Council, as a whole, is a weak unwieldy body, and liable to be ruled by any energetic and party section.

Pauperism of London.

OUR anticipations that the new President of the Poor-law Board would prove himself worthy of his appointment are likely to be verified. As soon as Mr. Goschen came into office a series of very valuable weekly returns of pauperism was commenced, the publication of which enables those interested in the subject to watch it and to apply to it exact methods of research. We have now to add that a comparative table has been prepared by the Board of the expenses of London out-door relief during the last three years and the year 1859, showing at a glance the march of expenditure in the several metropolitan Unions. The following is the official announcement:

METROPOLITAN OUT-DOOR RELIEF.

The following are the sums expended on the relief to out-door paupers during the parochial years 1859, 1866, 1867, and 1868 in the twenty-one metropolitan Unions which exhibit the largest increase of such expenditure:—

Unions.	During the year ended with Lady Day, 1859.	During the three years severally ended with Lady Day, 1866.	1867.	1868.
In the West District—	£	£	£	£

FREDERICK PURDY, Statistical Department.
Poor-law Board, Jan. 29.

Winter Climates and the Sanitary State of Winter Health-Resorts.

IN an article on winter climates we drew attention earlier in the season to some of the dangers encountered by invalids resorting to Southern health-resorts of which they know little, and about which their advisers were not sufficiently informed. Those remarks are bearing fruit We are in possession of many valuable facts and communications respecting these things, which it is our intention to lay before our readers. It is undeniable that some most serious mistakes are constantly made as to the kind of climate adapted for patients. Still worse, it is undeniable that such persons are frequently sent to places where they may easily fall victims to the state of the sanitary conditions. Bad water or bad drainage are almost universal in

Southern Europe, and, besides, these the diet and regimen of most visitors are the worst they can possibly be. We invite particular attention to the letter of Dr. Hawkins on the sanitary state of Nice, in our issue of Feb. 10th, and we call upon the physicians of Nice to say whether they have urged improvement upon the civil authorities, and whether any attention has been paid to such representations. Dr. Hawkins promises us authentic information as to the sanitary state of other health-resorts.

Medical Constitution of Brussels.

Within eight or ten days the medical constitution of Brussels has been completely changed. During almost the whole winter its sanitary state has been satisfactory, yet at this moment panic reigns far and wide.

The epidemic (for it is one) which has broken out in Brussels is a mucous fever, slightly different from typhus, but with very irregular phenomena. Generally this fever is characterized by great depression, by headache, anorexia, and thirst; by a tongue white or punctated with little red spots; by constipation or diarrhœa, slight heat of skin, slight reaction of the pulse, sleepiness, agitation, and epistaxis.

As yet the symptoms of this fever have not been very alarming, but in a few cases it has degenerated into typhoid and proved fatal. The civil and military hospitals are crowded, and the aristocratic quarters of the city are invaded by it as well as the poorer districts.—*Presse Médicale Belge.*

Medical Military Tailoring.

The following is a description of the new medical belts: For medical officers ranking with brigadiers and major-generals: Four rows of gold embroidery ¼ inch wide on black morocco shoulder-belt, gilt chased buckle and slide (no breast ornament). Pouch of black morocco leather, flap 6½ inches wide, 3¼ inches deep, and pointed—with three rows of ¼ inch gold embroidery—gilt chased V. R. and crown ornament. Sword-belt, black morocco leather with three rows of gold embroidery ¼ inch wide on the waist-belt, and three rows 3-16th inch on the slings; gilt chased clasp with silver lion and crown. For officers ranking under brigadiers: Three rows of gold embroidery on the pouch-belt, and two on the pouch and sword-belt as above described.

The Decimal System in Germany.

The decimal system has been adopted in Northern Germany for medical purposes, and certain States, including the Grand Duchy of Mecklinburg Schwerin, have been thereby compelled to change their Pharmacopœias. On a proposition from this State a commission of medical and pharmaceutical *savants* has been named to compile a Pharmacopœia common to all the States of the Northern Confederation.

Retrenchment in the Army Medical Department.

The following circular has been recently issued:—

Army Medical Department.

Sir,

1. It having been represented by several principal medical officers and others that there is undue expenditure of medicines, surgical materials, and dispensary sundries used in army hospitals, medical officers in charge will be good enough to personally supervise the issues under these heads.

2. At the periodical inspections principal medical officers will minutely examine the prescription books, to see that all articles used in the hospital, or issued to patients out of hospital, have been duly and properly entered, that the persons so prescribed for are entitled by the regulations to medical aid at the public expense, and that the totals of the ingredients in the prescriptions correspond with the quantities expended from the surgery stores. For this purpose detailed abstracts of the prescriptions written in the intervals of the inspections should be prepared by the hospital sergeant, and verified by the medical officer in charge.

3. Principal medical officers are required to see that where less expensive preparations are as efficacious, and as suitable as more expensive articles, the cheaper remedy is employed.

4. In forwarding returns of medicines, &c., the medical officer in charge will personally examine the same, verifying the quantities in the columns "expended" and "remaining," with the expenditure according to the prescription books, and the quantities actually remaining on hand; and the principal medical officer will, at the next inspection, satisfy himself that this has been done.

5. Before approving a requisition for a further supply, the principal medical officer will take steps to ascertain that there is no undue accumulation of any article in store, and that each item indented for will probably be required in the quantity demanded.

I have the honour to be, Sir,
Your obedient servant,
T. G. Logan, Director-General.

In Vienna, through the benevolence of Baron Anselm de Rothschild, who has given 200,000 florins for the purpose, an hospital for Jews is to be built. It is to contain 200 beds.

An elderly widow, while waiting in the surgery of Mr. Leslie, at Nine Elms, stole a piece of phosphorus from a bottle and placed it in her pocket. It ignited and burnt her so badly in the side that, by the advice of a surgeon, she was conveyed to the nearest hospital.

On Wednesday last, the Right Hon. G. J. Goschen, President of the Poor-law Board, paid a visit to St. Marylebone Workhouse, where he spent some time in inspecting the casual and sick wards, and other departments of the institution, in order to satisfy himself as to the system adopted there, it being generally admitted that the workhouse of St. Marylebone is one of the best conducted in the kingdom.

In Worcester Infirmary, a patient has just died in consequence of a mistake in giving him medicine intended for another person. At the inquest, the jury acquitted the officials of gross negligence.

It is said that typhus fever is raging to such an extent at Brussels, that the King and Court have left. All the private schools are removed from the capital.

Last Thursday, at a meeting of the Council, Mr. R. Partridge, F.R.S., late President of the Royal College of Surgeons, was re-elected a member of the Court of Examiners for a second quinquennial period, and Mr. A. Leggatt, who had been elected a Fellow at a previous meeting, was admitted as such.

The Board of Guardians of St. Pancras, at a late meeting, received the report of the General Purposes Committee, and agreed to adopt the same scale of relief of able-bodied paupers as is given in the parishes and unions at the East-end of London.

An interesting report at the annual meeting of the London Fever Hospital was presented by Dr. Murchison, the Senior Physician of the institution. The report stated that 3,657 cases were admitted last year, but that notwithstanding the mortality had been extremely low, being 15·2 on the whole. The institution has no endowment, and the committee appealed for increased public support.

If statistics are of any value at all, those which appear in the annual report of the Small-pox Hospital are deserving of note. The mortality in the cases admitted was 34 per cent. of the unvaccinated, while in those previously vaccinated it was only 6·5 per cent. We learn from the report, that the epidemic which had prevailed for five years has at length terminated, having ceased somewhat suddenly about the end of July or the beginning of August.

The Court of Directors of the Scottish Hospital held their quarterly meeting in the hall of the institution, Crane court, Fleet street, on the 11th inst., Dr. John Webster in the chair. The ordinary business being ended, a letter was read from one of the governors, complaining of the arbitrary allocation of the funds only to those children of Scottish parents who had been born in Scotland. After some discussion, Dr. George Webster gave notice of a motion for next meeting, that the bye-law referring to that matter be altered; that in future the recipients of the Hospital's annuities be admitted without reference to age or place of birth.

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. XI.

From the time that I undertook the responsible duties of "Proprietor" to that of which I now write, six months, minus a week or two, elapsed, and the professional fees received by me during the interval barely amounted to a tithe part of what they should have been, taking for my basis of calculation the representations made to me at the time of negotiating for the purchase of the "death vacancy," (as to the annual income derived from the practice,) by the parties interested in its disposal. Yet, in justice to the transfer agent engaged in the matter, I am bound to state that *his* picture of the Eldorado was fairly drawn—neither too highly coloured, nor varnished over so as to deceive nor to mystify. It was a faithful picture, but his clients smudged it subsequently—in fact, the fees that I received during the time stated were barely sufficient to meet current expenses and to keep in bodily vigour the Establishment, by which term you will please to understand, I mean one servant, Boey, Master Twig (an imperious black and tan terrier), and myself. Just then, too, the interesting relict and her retinue managed to give me a run of some miles on a *false* cry, and during my absence sacked the establishment and absconded with the contents, not sparing the least valuable requisite it contained!

On my return from the run to which I allude, I found the residence with that "draggled-tail" appearance so diagnostic of a quick fly—glass broken, bannister rails removed, walls bumped and scratched, and straw dust and frowziness everywhere. I found Boey sitting on the end of his professional basket, and Master Twig crouched with head on paws beside him. Boey was in tears.

"Boey, what's all this about?" I said.

"Gog-gone, Sir, the willans! bu-but I'll have law, so I will, for they punched my 'ead, they did;" and Boey sobbed, and sighed, and wriggled as he replied to my query.

"What is all *this* about?" I ask; "tell me, do you mean to say they gutted the house, bedrooms, and all, during my absence?"

"They did, the willans, Sir."

"And who assisted them in this, to where have they removed? Come, speak out, you rascal; for I suppose you have been playing their game for some time," and I seized Boey by the collar and shook him up after the manner of the wise woman, for I was sorely perplexed.

"Oh! master, dear master, let go, do dear, do, and I'll tell you all;" and Boey dropped on his knees, implored my desistance, and looked the impersonation of misery herself.

"There," I said, as I relaxed my grip, "there; be honest and I'll forgive you. But mark! if you deceive me I'll lock you up; come, speak!"

"Oh! master, dear, good master, the willans robbed you, robbed everybody, robbed and shot the moon in the broad day, and no one said "don't" but me, and they punched my 'ead, they did; bu-but"—

"Go on," I said; "quick, quick to the point, Sir."

"Oh! master, dear, on the death of the old 'un they went in for credit in a large way with the Oxford street and the Bond street folk, for silks and for jewellery, and 'nobby' things such like, on the strength of the old 'un's name and the big 'ouse; but the bills followed quick, and master"—

Boey ceased to speak. "Go on," I said.

"And, master, they thought you *wouldn't* stop by reason of no patients, and intended to *sell* the place again through the *Times*, and so to raise money"—

Boey again became silent. "Out with it all," I said.

"Well, Sir, that Dr. Sneak at the corner got any good patients that the old 'un 'ad about 'ere, and they weren't many. He used to come 'ere with a long face and a black pocket-book, by reason of which he does the parish and keeps a chemist's shop. And another 'un with a singin' missis—sleek like she were too—got more distant 'uns, and you only the bad 'uns, 'good enough for the money paid,' as was remarked. But master, dear master, I 'inted this over and over again, but you would not listen no'ow—'get along, Boey,' say you; you know you did, master, and now 'ere we are."

I was mute with astonishment, too indignant to utter a syllable—I utterly ashamed,—sad as my own case was—of the wicked, unmanly, ungenerous, and decidedly dishonest advantage taken of me by the pair of medical *touts*; and then, for the first time, flashed across my mind, with arrow-like swiftness, many circumstances that justified the belief in Boey's statement, including the *white smile* which one of those fellows invariably displayed whenever he passed me.

Wicked as the treatment I thus received from the "relict" was, in my mind it appeared to weigh even light as a feather in apposition to the selfish and "shoppy" conduct of those "professional gentlemen," from whom I should have received at least passive resistance. Was my case an exceptional one? Were there then in the vast metropolis but a brace of gentlemen who could act thus? I know not, but I could name a dozen instances where a repetition of it has been enacted far more recently, and ten times as many instances which displayed in the beautiful simplicity of nature's true gentlemen acts of medical practitioners, as unselfish as they were noble, as generous as they were manly, as hearty as the broad hand of professional fellowship could possibly hold out to sustain the weak and the weary. Some of those glorious sons of the noble profession of medicine justly stand high on the hill of fame, professionally and socially. Some of them, likewise, labour incessantly in the medical vineyard without the enjoyment of much of its pleasures or of its fruits, yet they are unpurchaseable, unseducible, and neither to be tempted, nor to be influenced, to seek worldly wealth by other than by legitimate means.

Here let me state that, many years after the time of which I have written, I made the acquaintance of a gentleman who, during a conversation with him, favoured me with the veritable history, from the cradle upwards, of one of the touts to whom I have alluded. I learned that he was educated *only* in the art of long faces; originally small boy to a petty shopkeeper, not even in the oil and colour interest—that he migrated on a rise of wage to assist the light parcel department in a drug warehouse—that being precocious and persevering, qualities to be admired and to be honoured within certain limits, he "got on" thence to be unqualified assistant to a kindhearted and humane practitioner—and finally, by means of certain specie derived from friends in the retail pewter-pot interest, the old certificate dodge, and the lax manner in which professional examinations were *occasionally* conducted some years ago. Having now attained the semi-patriarchal age of "forty odd" years, he "got through," and finally *did* the parish, as a consequence.

On ascertaining exactly how matters stood—"the why and the where *to*" the relict and her company had removed—my first impression was to seek advice and assistance from the police authorities, and to compel the culprits—which they morally were—to yield up the share of property to which I had yet a claim. But I was quite unused to law and to the police, and as I believed an exposure of the kind, however successful at the time, might lead to misrepresentation, and raise the old and sometimes false cry of the "strong persecuting the weak," (?) resolved to put up with the insult and the loss, to nail my colours to the ideal mast, and to stick by the ship whilst I had even a sea leg on which to stand. I resolved rightly, for it followed, the "fixings" removed from my residence were stored in what Boey styled a "pontineckintor," and sold by auction a few days afterwards.

Without drawing the long-bow of exaggeration, the term "desperate" might now be applied to my case. I held the lease of a large house, 'tis true, but it was an empty one! with large rent and proportionably larger taxes, and rates nearly due, and with little money to meet them. What step should I take? Wretchedly fail? Cut the concern by one clean sweep? Write to my relation, state my case, and act on his advice? Or ought I to hold my ground (as I first resolved) and fight the world upwards as a man, even at the risk of experiencing a *broader white smile* from that parish tout, or any other sneak like him? My mind was made up! Stop in possession, hold my ground, and fight it through, I would endeavour.

During the time that I debated the point, the seat I occupied was an improvised one, formed by my portmanteau upended. Boey, with elbows on knees and chin in hands, still occupied his professional basket, and in these positions we for a considerable time remained. Boey was the first to break the silence.

"Master, shall I go for mother?" he asked.

"Mother! whose mother?" I replied; the term acting as a spell on the words as I uttered them.

"My un, master; she's good as gold, Sir. *She'll* make us all right, she will. Why there, we have nothink no'ow, nor nothink to eat with it, nor to eat it on, the willans!"

"Boey, a good mother is even better than gold—better, better than gold, Boey—far, far better than gol—"

I attempted to enlighten Boey by a running litany of words, heroic and triumphant, to the praise of mothers, for my mind shot back to her of hope and of sorrow who called me son—whose frown upon me I never yet experienced—whose loving smile was ever waiting my acceptance of it—whose every want yielded to my wayward youthful eccentricities—and whose soothingly mild, graceful, and affectionate words and influence were ever by me, to advocate patience, discretion, and good sense, at times when stock fed youth and inexperience, coupled with cloudy notions of "what ought to be," raised perhaps my temper to a boil, and occasionally beyond it. And now I found my tongue inert, and my fauces dry and too parched to permit the words I desired to utter a free passage to my lips.

Boey looked into my face! Even the least sympathetic that may read these hurried pencillings may surmise what the boy beheld there. "D'don't, master," he said. "I'll—I'll go for mother." Boey rose from off his basket, hurried from the apartment, accompanied by "Master Twig," and left me in the enjoyment of a clear stage and a favourable opportunity to think of the past.

After a little time Boey re-entered the apartment, accompanied by Mistress Bazil Pod, who suggested so many things, and did so many things, and so willingly, too, in order to improve matters, that ere the close of the following day I was as comfortably, if not so luxuriously lodged, as heretofore, and firmly impressed with the belief that mothers make kings, and are better than gold.

Quid Nunc.

Correspondence.

SUGGESTIONS IN MEDICINE.—No. I.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The writer of the following letters is a medical man of mature age, of considerable experience in various parts of the world, and not altogether unknown in the profession; but he has been for a long time disabled from active practice by the rheumatic gout, and is now so completely its victim, that he is utterly and hopelessly paralyzed. His sight, moreover, has failed so much latterly from congestion of the tissues of the eye—a part of the same complaint—that he is scarcely able to read what he pens. Yet he has thought much during the tedious hours of inaction, and fancied he has made valuable discoveries on points of practice. Unable to carry out these favourite schemes, and somewhat depressed in consequence, he is now anxious to devote his remaining powers—such as they are—to their elucidation, in the hope that others more favoured with health and strength may adopt and bring them to maturity. They must be regarded more in the light of suggestions than experiences. No research can be made. Infirmity forbids much reading. Hence the writer may have blundered on the ideas of others. Yet, as far as he knows, his notions are original. That their promulgation may eventually benefit the afflicted is his unselfish and earnest desire. A feeling of duty alone prompts him to a task, now irksome and painful, which, under other circumstances, would be extremely pleasing. The first suggestion is with respect to—

BLOOD DISEASES AND THEIR TREATMENT BY TRANSFUSION.

There are many complaints known to pathologists under this title—diseases that are believed to pervade the entire frame, and to depend on some derangement or abnormal condition of the circulating fluid. Into the pathology of the subject I have no wish to enter. It is almost sacred ground. Great obscurity attends it. The most consummate talent and determined industry have, as is well known, been employed in this department of research with but indifferent success. The test-tubes of the chemist, and the most powerful lenses of the histologist, have failed to discover the latent causes of mischief. I believe I am right in stating in general terms that many diseases depend on the presence of a subtle poison in the blood; but that in the present state of science it is impossible to demonstrate either its separate existence or exact nature. Pathologists believe it to be one thing or another—each has his theory—but for anyone to prove that his right is impracticable. Moreover, the cure is equally difficult. To eradicate the poison from the blood—to neutralize or subdue it—is too often beyond the power of man. Medicine fails. Diet—regimen—affect it little. The morbid diathesis remains, and generally speaking increases in intensity in despite of every effort. The gouty man remains gouty, the consumptive phthisical, the cancerous carcinomatous to the end of existence. Of course there are apparent exceptions, but these prove the rule. Nature also occasionally effects a change. But man has usually found it impossible to alter the diathesis.

Under these circumstances, it is now proposed to adopt a new plan—one that strikes at the very root of the difficulty. These are days for bold innovation, and why not in medicine? It is suggested, that a portion of the unhealthy blood should be abstracted, and that an equal quantity, that is of a healthy character, substituted in its place,—to extend the system of transfusion, in fact. It may even be advisable in some cases to substitute such blood as is of an opposite diathesis. For often the conditions of the system appear to be opposed—the gouty and phthisical, for instance. But this would give rise to a new system of investigation. If this novel purpose of transfusion be adopted, pathologists might well study the subject under a new aspect—from a different point of view in truth.

The proposition now before us is, that a portion—say a pound, more or less—of sound, healthy blood, should be transfused in lieu of an equal portion contaminated or diseased, in the hope and reasonable expectation that a part would, in Scripture phrase, "leaven the whole." It may act both medicinally and vitally upon it. By repeated substitutions a large proportion of the unhealthy fluid may be eliminated. In practice I imagine it would be rarely necessary to resort to this alternative; the one operation would, I firmly believe, effectually answer the purpose of an alterative, so that good blood would afterwards be generated.

Of course, a variety of objections could be offered to this system; but I believe a satisfactory answer may be given to each. Few men had studied the subject of transfusion of blood more than the late Sir Charles Hastings. He had made some forty or fifty experiments on animals, chiefly sheep, with the view to test its value in cases of hæmorrhage. When we met, many years ago, at Droitwich, I explained my views, and he was pleased to regard them with favour. The apparatus I proposed to employ for effecting the transfusion he thought extremely well adapted to the purpose, and infinitely superior to that already in use.

It remains now to describe this apparatus, and say how it is to be put in action. I shall find some difficulty, though, in making myself well understood without the aid of woodcuts for illustration. If any gentleman, therefore, should feel disposed to adopt my views and give them a practical bearing, I shall only be too happy to afford him any further aid in my power.

The exact statistics I do not know, but I believe transfusion of blood has not been extensively practised in this country—some eight or ten times, perhaps, altogether. It has been used solely to restore the system when exhausted by hæmorrhage, as in flooding, &c. The transfer has been effected with an ordinary syringe, such as that employed for the ear, or as a stomach-pump. The clumsiness of such an instrument for such a delicate operation must be obvious. The blood is always liable to be chilled, nay, even clotted, ere it can be injected. A greater danger arises from the introduction of air into the veins, which would be, of course, immediately fatal. In the hands even of the most skilful operator, one or both of these evils might ensue.

What I propose to use is not so simple, certainly, but is far more delicate, accurate, and safe. Tubes of caoutchouc, or india-rubber, about two feet long and half an inch in diameter are fitted with stop-cocks at each end. Attached to each extremity are also small plates of metal, from the centre of which project short flattened metallic tubes. These are intended to be inserted into the openings in the veins made by the lancet, and fixed securely there by straps most carefully adjusted. A light stand would sustain a trough of warm water, in which the greater part of the tube would rest in order to ensure due temperature. Two, or even three, of these caoutchouc tubes would be required.

In performing the transfusion, the operator would first thoroughly soak the tubes in warm water, as well as carefully fill them with the same. Then, passing the elastic material between his finger and thumb, he would squeeze out every drop of the water, and prevent the admission of air by closure of the valves.

The patient and his friend, the receiver and donor of the vital stream, being placed in convenient and easy positions with respect to each other, a vein would be opened in the adjoining arm of each, and the two limbs connected together by means of a tube carefully adjusted and thoroughly secured. A vein in the other arm of the patient would then be opened and have a tube affixed in the same way. The whole kept properly warm by means of the troughs.

When all agitation had subsided, the operator would partially open the valve of the tube attached to the donor and allow the tube to be slowly filled with blood by the elastic action of the caoutchouc. When completely expanded, the valve would be closed once more. To transfer this blood into the patient's arm it would be necessary merely to open the valve on that side and squeeze the fluid in by means of the finger and thumb, securing its return by turning the tap. At the same time, if it were considered necessary, an equal portion of diseased blood could be drawn off from the other arm of the patient and squeezed into a basin. In this way all danger from repletion could be avoided. The first transfusion would thus be complete.

After an interval, this series of operations could be repeated until the necessary or intended quantity had been administered. And here it may be mentioned that the tubes should be of such length and calibre as to hold a certain definite quantity—say two ounces each—so that the amount of blood abstracted and substituted could be determined with accuracy. It will be seen also, that there would be no necessity to hurry the process. It might extend over hours if advisable, so that the interests of both donor and recipient could be consulted. It is quite clear also, that an adroit operator could, if necessary, transfer a full pound of blood or more in a few minutes.

Some people will be ready to exclaim at this juncture:—"But where is the blood to be found? Who is willing to submit to such a loss as a pound or more of his vital fluid? No one in health and in his senses, surely?" Excuse me. The gradual loss of even a larger amount could be, as it has often been, borne with perfect safety. It would injure no really hearty man, seriously or permanently. Blood is readily replaced in the young and vigorous. Indeed, it is well known that repeated small blood-lettings lead to plethora. And then as to the will to make the sacrifice. When has the husband failed to come forward and be bled when the wife of his bosom, the mother of his child, has been in jeopardy? Surely a relation or a friend could be found who was willing to make some sacrifice for one dear to him. Besides, there are always to be found those who, for reasonable reward, are ready to sell, not their blood only, but their lives. In truth, if there were much demand, there would be ample supply of this as of other things. That difficulty would, I feel persuaded, speedily vanish.

As to the fancy of other people's blood producing change of character, or madness, that, I veritably believe, is all moonshine. No woman has hitherto been injured in that way by transfusion, and the experiments on animals clearly show that blood is blood all the world over. The difficulty is in the introduction of so great a novelty. Yet he must have been a bold man who first opened a human vein. No one is now horrified at that operation except the homœopathist.

Your obedient servant,

Bath, Nov., 1868. C. TOOGOOD DOWNING, M.D.

MEDICINE.

THE METHOD OF EMPLOYMENT OF ANTI-PERIODICS.

There is no conclusive evidence that admitted anti-periodics ever produce curative results when administered during, or even a short time before the accession of a paroxysm of intermitting or remitting fever. In neuralgia they occasionally afford relief when administered during a paroxysm of pain; but such instances are so rare as to render it probable that they were accidental coincidences. To secure their curative effects, it does seem that they should be in full operation some time before the paroxysm begins, and that their action be decided in every case. Such is the experience of the writer.

For a number of years the writer has employed anti-periodics, guided by these views, and he is confident his success in treating intermittents greatly exceeds that following the methods generally in use. After such preliminary treatment as the case may require, he administers the anti-periodic in a commanding dose, seven or eight hours before the expected paroxysm; and to ensure the early action of the remedy, especially quinine, upon the duodenum, liver, and spleen, which he thinks are the organs, more particularly the duodenum, in which the remedial action begins, he has been in the constant practice of combining a mild cathartic agent with the anti-periodic to hasten the passage of the remedy from the stomach into the duodenum. By this means the anti-periodic is conveyed sooner into the duodenum than if administered without the cathartic, where it at once sets up the actions peculiar to it, in advance of the expected paroxysm and in time to prevent it.

This method of employing anti-periodics was suggested to the writer, some fifteen or twenty years since, by the report of a case of tertian intermittent he received from an eminent practitioner of Virginia. In this case, quinine was the anti-periodic employed, and it was administered in the form of a simple pill only a few hours before the expected paroxysm, in quite a heroic dose. The remedy failed to prevent the paroxysm, which was quite a severe one, but seemed to prove remediate with the next one, which failed to occur, and without repeating the anti-periodic. The medical gentleman who reported the case was at a loss to account for the non-appearance of the second paroxysm, so long after the anti-periodic was administered, and the writer explained it by supposing that the remedy did not reach, or impress the duodenum until late the next day, by reason of the violent symptoms which accompanied the paroxysm it was given to ward off. Since the occurrence of this case, the writer has constantly employed quinine as an anti-periodic in intermittents, from seven to ten hours before the expected paroxysm; and to ensure its certain action as such upon the duodenum, he invariably combines some gentle cathartic agent with it, for the purpose of hastening its passage from the stomach into that organ. In a vast number of cases this simple method has been successfully employed. Indeed, no other has been resorted to now more than fifteen years since its first trial, and with few, if any, failures.

To ensure the complete anti-periodic protection the remedy should be repeated several times after the paroxysms have ceased to recur; and a single commanding dose of quinine compounded, and timed as already stated, will be sufficient to meet each paroxysm in a large majority of instances. If the case has been severe, the quinine might be repeated oftener, perhaps as frequently as three or four times, and, when discontinued, some bitter infusion—Huxham's elegant tincture of bark, or the bark in substance—should be used and kept up for several weeks.

In some instances quinine puts a temporary stop to the paroxysms of intermittents, the disease recurring from slight exposure to the vicissitudes of temperature, or from an imprudent meal; and such examples now and then prove exceedingly intractable.

For a number of years the writer has regarded the duodenum as the organ upon which anti-periodics chiefly, if not primarily, act as therapeutical agents in intermittents, especially quinine, and that remediate actions beginning there are soon propagated to the spleen, liver, and nervous centres. That the spleen is often impressed by quinine, decidedly, will not be denied, and hence it is occasionally prescribed in enlargement of that organ consequent upon intermitting fevers. He had also long believed that quinine was too freely and indiscriminately employed in the treatment of intermittents, nay, even in many other diseases. A single dose of it, if properly timed, and of carefully adapted power, will rarely fail in its anti-periodic remedial effects. But experience establishes the important fact, that it does not fully protect the constitution against relapse in numerous cases in which it is employed.—*Richmond Medical and Surgical Journal.*

DEVELOPMENT OF TÆNIA BY THE USE OF UNDER-COOKED MEAT.

Dr. Grilli has observed, within six months, six cases of tænia in children aged less than three years. He attributes this disease, commonly so rare in children, to the use of half-cooked meat. We know, in fact, since the researches of the helminthologists on the development of intestinal worms, that tapeworm in the human intestines are the product of the cysticerci found in pork and sometimes in beef.

The six children to whom allusion is made had all extensively used this sort of food as a remedy suggested by Dr. Weiss for chronic diarrhœa. Without depreciating the merits of that therapeutic agent, the author declares that, however excellent it may be, he would not advise its use until some chemical or mechanical means are discovered to replace heat in destroying the cysticerci. We venture to remark that to act thus would be, for fear of a problematic and curable disease, to set aside a precious resource, the only one which often is left to save the unfortunate child from certain death. —*L'Imparziale.*

PHARMACY.

ADULTERATION OF PRECIPITATED SULPHUR.

Why is precipitated sulphur still usually adulterated to a scandalous extent with what may be termed plaster of Paris,—hydrous sulphate of calcium? Nearly every book on chemistry and materia medica states that instead of being made by mixing hydrochloric acid and polysulphide of calcium, it is often prepared by the reaction of sulphuric acid and the sulphur salt, the result being precipitated sulphur (identical, so far, with the official article—*Sulphur præcipitatum* B. P.), but mixed with more than an equal weight of the calcarious mineral compound, which when well dried constitutes plaster of Paris. From the following table it will be seen that out of eight samples which I recently purchased (for quite another purpose) within an area of a mile, only one was pure, one contained nearly half its weight of calcarious matter, and each of the others was actually two-thirds impurity and only one-third precipitated sulphur. In explanation of this condition of things, the statement is commonly made that the public has become so accustomed to the satiny appearance of the impure article (due to the selenitic character of the adulterant) as to regard the pure with suspicion, often refusing to purchase it. I cannot believe in the general application of this explanation. The public, surely, place too much confidence in a pharmacist's knowledge of drugs to persist in refusing a pure in favour of an impure chemical. Therapeutists cannot hope to arrive at a rational system of medicine unless the followers of pharmacy combine to crush the practice of adulteration. Precipitated sulphur is, doubtless, an exception to the general rule that drugs are less adulterated now than formerly, but clearly there is room for much improvement.

Chemists and druggists, their customers, and medical practitioners, should refuse to purchase any precipitated sulphur which leaves a white ash when a little is burnt off on the end of a table-knife or spatula.—*Professor Attfield, in the Pharmaceutical Journal.*

PAPER FILTERING.

A correspondent of the *Pharmaceutical Journal*, with reference to an article on this subject in the January number, observes:—A very simple, and for many practical purposes a very satisfactory plan, occurred to me lately, and I find it work remarkably well. I do not allow the paper to touch the glass at all or as little as possible; and this is about all that can be done for the perfecting of a paper filter. This is managed by introducing into the filter a coil of thin wire, formed into a cone roughly corresponding to the inside of the filter. I say *roughly*, because were it too nicely done, the wire might lie close to the glass. Iron wire does well enough for many things, but silver, platinum, or any other metal may be substituted. I tried a sort of cage with upright ribs, these allow the paper to clasp close to the glass. Very neat "filter holders" could be made on this principle, and I hope to see them shortly for sale.

VARIABLE STRENGTH OF PHARMACEUTICAL PREPARATIONS.

In a recent discussion at the Pharmaceutical Society on the inconstant strength of aq. laur. cerasi, Professor Redwood said—He looked upon cherry-laurel water, as an article of pharmacy, in the light of an abomination; he always had viewed it in that light, and had always protested against its being retained in the Pharmacopœia; but he had been met by the statement of medical men that they had been accustomed to use it, and whatever chemists might say about the variableness of its composition, they had found certain advantages attach to its use, and wished to be allowed to use it. They had been told, however that great value was attached to it on the Continent, and also that those who had used it in this country had found a benefit from it which they had not experienced in the use of hydrocyanic acid, and they were also reminded that there were many preparations used in medicine of a not very definite nature, which sometimes were found to answer the purpose of the physician better than those which were more definite. In reference to this very article, he had been reminded of the difference that existed between the preparation which was introduced many years back under the name of chloric ether, and that which was now considered a more definite and uniform representative of it under the name of spirit of chloroform. The old chloric ether differed probably from the present spirit of chloroform to about the same extent and somewhat in the same way that cherry-laurel water differed from dilute hydrocyanic acid. The one was of a definite and uniform strength, and a perfectly comprehensible preparation, and the other was an indefinite mixture of variable products, which were administered in an unpurified state. There were, however, those who still held to the old chloric ether as being preferable to the spirit of chloroform. That was one case, and there were many others of the same kind. At their previous meeting Dr. Attfield had said in reference to a certain preparation of opium, that if the efficacy of opium depended on morphia, why did not physicians use a solution of morphia, and have something perfectly definite in form. That was a very short cut made to attain to what theoretically appeared certainly a correct and satisfactory mode of proceeding, but it was not a method that would generally meet the views and requirements of the medical profession. They would say that if you took morphia or any of its salts, and if they took a certain preparation of opium and administered them, they found perfectly distinct and different results. In like manner with quinine, which was a definite preparation of cinchona bark; they could prepare sulphate of quinine perfectly pure, and could make a solution of it, the composition and strength of which they could tell precisely, but nevertheless, there were medical men who would take certain preparations of the bark which they said produced effects different from those of sulphate of quinine. While this was the case they must admit the superior knowledge of medical men, and endeavour to provide those preparations which were required by the profession.

CHLOROFORM IN THE URINE.

The urine of patients who have inhaled chloroform, when tested with sulphate of copper and potash, gives a copious indication of the presence of sugar. The result, however, is not due to sugar, but to the chloroform. Traces of the latter substance in the urine caused a reduction of the oxide of copper in precisely the same manner as glucose. The presence of chloroform in urine may be detected by causing a current of air to bubble through the urine, then to traverse a red-hot porcelain tube, and finally to pass through a Liebig's bulb containing a solution of nitrate of silver. The vapour of the chloroform diffuses into the stream of air, is decomposed in the heated tube, and the resulting chlorine precipitates the silver solution.—*Journ. de Pharm. d'Anvers.*

◆

It has been ruled by the Government of India that in the absence of the surgeon in medical charge of a British regiment on leave on private affairs in England, his *locum tenens*, being an assistant-surgeon, is to receive the medical-charge allowance of £15 per mensem.

ARMY MEDICAL SCHOOL, NETLEY.

Examination of Candidates for Assistant-Surgeoncies in H. M.'s Royal and Indian Armies, held at the close of the 17th Session of the Army Medical School.

A. Written Examination.

(Three hours allowed for each subject.)

I. Military Hygiene (Prof. E. A. Parkes, F.R.S.), Monday, 1st February, 1869.

1.—What amount of fresh air per hour ought to be supplied for an adult? What are your reasons for stating this amount? How would you ascertain the direction and extent of the movement of air? What are the chief impurities in air, and what are supposed to be their effects? How would you examine for them?

2.—What amount of labour is undergone by the soldier in time of peace? How would you estimate this if you were required to give a numerical expression for it? How does the labour performed on a march of twenty miles with and without weights compare with the labour of a common mechanical trade?

3.—Contrast the diseases and the mortality of the West and East Indies, and state what precautions are necessary for the prevention of yellow fever and cholera respectively.

II. Pathology (Professor W. Aitken, M.D.), Tuesday, 2nd February, 1869.

1.—On the occurrence of an epidemic of fever (such as recently prevailed at Malta and the Mauritius) the phenomena of which fever did not conform to the phenomena of other known fevers. What are the systematic investigations of a clinical and pathological kind which you would institute to determine the nature of the fever, its course, and its duration?

2.—Since 1838 it has been every now and again asserted that the stools of cholera during a certain stage of the disease contain forms of fungi in great abundance; the same has more recently been alleged of other diseases. It has been also alleged that such fungi constitute the "contagium" of the disease.

Name (and describe sufficiently to identify) the elementary structures of microscopic fungi.

The use of certain re-agents is absolutely necessary to distinguish fungi, therefore name the best re-agents, and state their uses, mentioning at the same time the forms or substances (organic or inorganic) with which the microscopic elements of fungi may be confounded.

3.—Private Michael Mulcrone, aged 33, had completed ten years' service, and was admitted to Netley, from on board ship from India, on the 14th November, 1868. He had served for four years in the East Indies and four years at the Cape of Good Hope. On admission at Netley he was sent to the surgical division for syphilitic rupial ulcers of the body and extremities; but on the day following his admission he was transferred to the medical division with the following symptoms, namely, dyspnœa, with severe pain in the left side, accompanied by the expectoration of pneumonic sputa. There were also present thirst, flushed cheeks, heat of skin (temperature, 102·3), and quick pulse; dulness on percussion over both lungs, especially posteriorly; pleuritic friction sounds, and small crepitations heard on the left side, with inspiration.

On the third day after admission there was increased dyspnœa, difficult expectoration of tenacious, rusty-coloured expectoration, with an evening temperature of 103·8. On the sixth day after admission the temperature fell to 99·4, and respiration was less difficult. On the eighth day the respiration again became hurried, the cough more frequent and harassing, great thirst; large and small crepitant *râles* were heard over both lungs posteriorly. On the ninth day there was great restlessness; the respirations were 42 per minute; the pulse 135, with a temperature of 102·1°. Abundant expectoration of purulent sputa. On the tenth day the respiration became more difficult and more hurried; perspiration profuse; temperature 102·1°; pulse very rapid, with lividity of countenance. On the eleventh day he was sinking; pulse 138, intermittent; respirations, 48 per minute; a temperature of 103·2°; and at midnight he died.

1.—What were the evidences of syphilitic lesions?

(*a*) On penis.
(*b*) On skin.
(*c*) On lymphatic glands.
(*d*) On testicles.

2.—What were the lesions seen in the tonsils and fauces, larynx and trachea, and connective tissue surrounding the œsophagus?

3.—What were the lesions seen in the pleura, and the lungs, and the liver?

4.—Write a commentary on the whole case—
  (*a*) In relation to the syphilitic lesions.
  (*b*) In relation to the lesions associated with the symptoms immediately preceding death.

III. Military Surgery (Prof. T. Longmore, C.B., Deputy Inspector-General), Wednesday, 3rd February, 1869.

1.—Describe the leading characteristic features and general treatment of incised, punctured, and gunshot wounds as they are met with in warfare.

2.—Explain the successive steps of the process by which you are enabled to determine that the refractive quality of the eyes of a soldier sent to you for examination is perfect; or, if found defective, how you establish the kind and degree of defect which exists in them, or in either of them.

3.—(*a*) Give a sketch of the system on which diets and extras are ordered to patients in military hospitals.
  (*b*) Mention the names of the diets in the authorized scale.
  (*c*) State the composition of any one of them.

IV. Military Medicine (Prof. W. C. Maclean, M.D., Deputy Inspector-General), Thursday, 4th February, 1869.

1.—What are the types of fever usually seen in unsanitary camps and garrisons? Describe them and the mode in which you would deal with them as regards prevention and treatment.

2.—A. B., a soldier, ætat 40, 17 years' service, 10 of which were passed in India, presented himself at Netley in the following condition:

Is thin, has a sallow anæmic complexion, but is not jaundical. No anasarca or ascites, abdominal veins not enlarged, appetite bad or capricious, suffers from indigestion and severe diarrhœa from apparently slight causes, the motions being large, watery, frothy, voided with violence but without pain, and having no dysenteric odour. His Medical History Sheet shows that he suffered from syphilis in England before going to India, from the same disease in Bengal, both in its primary and secondary forms, from repeated attacks of intermittent fever, and from long-continued dysentery. On examination:—The respiratory and circulatory systems are found to be fairly normal; the liver extends as high as the right nipple, and downwards to the level of the umbilicus; its consistence is firm without being indurated, smooth, not elastic, painless; the gland is reported to have attained to its present size slowly, and there is no history of previous hepatic inflammation; the only complaint made is of a sensation of weight and fullness and inability to lie on the left side; there is some enlargement of the spleen; the urine is above the normal quantity, pale, of low specific gravity, and contains albumen and hyaline casts. Although not noted as an intemperate soldier, the patient admits that in India he daily consumed more than his spirit ration.

What is this man's disease, and how would you treat it?

3.—Give the diagnostic points:
  (*a*) Of abscess,
  (*b*) Of hydatid tumour,
  (*c*) Of fatty enlargement,
  (*d*) Of cancer of the liver,
and the treatment of the two first conditions.

Pathology.—Practical Examination, Saturday, 6th February, 1869.

1.—Examine the fluid in the test-tube and name the vegetable structures contained in it. State how you have distinguished them.

2.—Examine the portions of viscera placed in the dishes. State of what organ each is a part, and describe its morbid conditon.

3.—Name the parts of the body shown in the preparations numbered respectively 1, 2, 3, 4. Describe the lesion or lesions which each of them illustrate.

4.—Determine the magnifying power of *any one* of the microscopes, and append the scale used.

NOTICES TO CORRESPONDENTS.

Notice to Subscribers.—Subscriptions for the year ending Dec. 31st, 1868, are now due. Subscribers resident in England will greatly oblige by forwarding the usual amount, 22s. 6d., either by cheque or P.O.O., made payable to A. A. Tindall, 20 King William street, Strand, London.

Subscriptions in Ireland to be sent to 3 Lincoln place, Dublin, and in Scotland, to Maclachlan and Stewart, South Bridge, Edinburgh.

Advance subscriptions, 21s. 8d. post free per annum, for the current year, can also be paid as above.

The Quid Nunc Papers.

"An Admirer of your Journal," Dr. Pratt, R.N., Russell square, Mr. T. Hagers, Deptford, and others, are thanked for their complimentary notes on these papers. The present series will be finished in two more "Pencillings." Whether or not they will be resumed is not yet decided upon. The object of our facetious contributor has been to point out some of the existing anomalies and abuses in the public departments, which he considered could be best done in a jocose and lively style. Serious discussion being calculated to lead to personalities and to excite angry feelings, we are at all times anxious to avoid.

Qui fit Mæcenas.—Many thanks for the information. We assailed the appointment *in re* Oscar Clayton on public grounds, and the publication of personal details would not, we think, be suitable.

"Observations on the Treatment of Psoas Abscess," by Thomas More Madden, M.R.C.S., &c., received.

Mr. Connoly (Belfast).—"The Ulster Examiner" has not come to hand.

Received and shall appear in an early number, "Contributions to Clinical Surgery and Medicine," by Professor Hargrave.—1st. Injury of the Lumbar Region of the Spine, with some Peculiar Symptoms. 2nd. Successful Extraction of Needles, with and without the aid of Chloroform.

"On the Treatment and Prevention of Pauperism and Crime," by Henry MacCormac, M.D. Proofs shall be sent in due course.

AND BED ROOM FURNITURE.
An ILLUSTRATED CATALOGUE, with prices of
1,000 ARTICLES OF BED ROOM FURNITURE,
sent free by post on application to
FILMER and SON,
UPHOLSTERERS,
31 and 32 Berners street, Oxford street, W.;
Factory, 34 and 35 Charles street.

MR. HOWARD, Surgeon-Dentist, 52, Fleet-street, has introduced an entirely NEW DESCRIPTION OF ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble the natural teeth as not to be distinguished from the original by the closest observer; they will never change colour or decay, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr. Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed teeth stopped and rendered sound and useful in mastication. —52 Fleet street. At home from 10 till 5.

T. and H. SMITH'S Codeia Lozenges.
These Lozenges have a remarkable effect in allaying
Cough and Irritation of the Throat and Chest.
Prepared only by T. and H. SMITH and CO., 21 Duke street, Edinburgh, and 69 Coleman street, London; and to be had of any Chemist and Druggist, in Boxes at 1s. 1½d. and 2s. 9d, each.

ON THE MODE OF ACTION OF THE CHOLERA POISON.

By **ARTHUR ERNEST SANSOM, M.D., M.R.C.P.**,

Physician to the Royal Hospital for Diseases of the Chest, City Road.

IN my former communications to this Journal (November 6, 1867, January 15 and 22, 1868) I endeavoured, in as strict a manner as a limited space would permit, to ascertain from a logical analysis of existing facts the probable nature of the first cause of cholera. The result attained was the expression, that cholera is due to the operation of a material, communicable, organized poison.

I promised to reverse the method employed, and to endeavour, so far as I should be able, to "demonstrate each link in the physiological chain of causes" by which the phenomena of cholera are produced. I need only call attention to the great difficulties which attend such an inquiry as this. What disease in the whole range of medical experience is there whose phenomena can be traced step by step with any absolute precision? That some such test, however, should be applied to a theory advanced to elucidate the causation of disease I thoroughly agree—the analytical method corrects the synthetical, and *vice versâ*.

Since my last communication, the Registrar-General has given an authoritative exposition of the doctrines deduced from the great records accumulated during the recent as well as the more remote outbreaks of cholera in England. It is perfectly evident that the conclusion produced in his mind, as in the minds of those who have most deeply studied the evidence, is that "cholera is propagated epidemically by a material substance, analogous in its nature to the substances which produced, under given circumstances, small-pox, cow-pox, syphilis, erysipelas." This cholera-matter is first termed *cholerine;* then, to distinguish the cholera-producing particles which constitute the cholerine, the term *cholerads* is employed. (Supplement to the Twenty-Ninth Annual Report of the Registrar-General of Births, Deaths, and Marriages in England, 1868.) We will assume the existence of a germ which has the power of producing cholera; the first question which we are to attempt to solve is—

What are the physical qualities of this cholera germ as observed external to the animal organism?

In the first place, it is probable that the cholerad is a body of extreme minuteness. The very fact of its having eluded for such a series of years the most careful scrutiny of observers, who have employed the highest powers of the microscope, is *à priori* evidence in favour of this proposition. The investigation of the phenomena of vaccination has shown how almost inconceivably minute are the particles capable of inducing disease. Not only are these said to be, under the highest powers, molecules scarcely visible, but the researches of Chauveau have shown that if vaccine lymph be diluted with 150 times its bulk of matter, and a milligram of the solution be conveyed on a lancet-point to an animal organism, it is capable of inducing the phenomena of vaccine disease. According to Beale the organized bodies capable of producing cattle plague must be less than 1-50,000th part of an inch in diameter. Analogy, therefore, lends colour to the hypothesis that zymotic matter (and by inclusion cholera matter) is composed of particles at the utmost verge of vision.

If we come to the question of the origin of the cholera germ we shall find that this is wrapped in a mystery probably never to be penetrated. The probability seems to be this—that whereas there existed throughout many ages an organized material capable of producing, under certain conditions of climate and individual susceptibility, symptoms of diarrhœa of greater or less severity, at a certain period, under a peculiar combination of conditions, this organized material became endowed with new powers, which it transmitted to generations of its kind. It was supposed, from the observations of Professor Hallier, that the clue to the origin of the first germs of cholera might be found in the following observation:—A peculiar fungus (urocystis) is found in the intestinal canal of the victims of cholera; a similar fungus is also found in certain conditions of diseased rice; diseased rice is capable of producing some of the phenomena of cholera: therefore it is probable that the use of diseased rice by the natives of India was the first cause of the cholera outbreak. I shall presently show how greatly surrounded with fallacies are the propositions and the conclusions. In the first place, however, we may inquire, "In what essential point is there an agreement of testimony as to one of the cardinal conditions of cholera origin or cholera propagation?" The answer to this, I think, cannot be questioned—viz., a high temperature. This condition, then, is observed to be identical with that which common observation shows to predispose to the fertility and the activity of germs.

Now comes the objection of those who urge that we are equally justified in assuming, at certain times and seasons, the existence of new materials as of new conditions. They uphold the theory of so-called "spontaneous generation;" they say that this new poison, which they conceive to have been generated in Lower Bengal in 1817, was generated and propagated in London in 1866. They say that the forms of inorganic material are occasionally presented in such guise that the ablest exponent of the "vital doctrine" cannot distinguish them from living things. But surely it is for them not merely to object but to prove. They urge that such inorganic matter may, under correlated physical influences, assume the properties of an organized body; if they can show by actual demonstration that such inorganic matter, subject to the physical influences which they can bring to bear upon it, becomes endowed with the *powers* as well as the *appearances* of living beings, well. They have established their point; they have produced their Frankenstein. But if not, it is for us to lean to the side whereon there is the greatest amount of evidence, and with Pasteur and with Beale agree that all living matter comes from pre-existing living matter, however unable we may have been, through the imperfection of our powers, to detect the latter. It seems to be rendered very probable (see, on this point, Beale's "Microscope in Medicine," third edition, p. 203) that the same germinal matter, under different conditions of pabulum and of force, assumes distinct properties. Thus: "The germinal matter of tissue, being supplied with an increased quantity of pabulum, may give rise to pus . . . but pus differs in *power* from the germinal matter from which it was derived. . . The germinal matter of cuticular epithelium may give rise to the peculiar hard material of which the so-called 'walls' of the epithelial cell consist, and this same germinal matter of epithelium, if freely supplied with pabulum, may give rise to pus." By parity of reasoning, the germs which, under certain conditions, produce choleraic diarrhœa may, under certain others, produce cholera, for certainly there seems to be a probability of even less difference between diarrhœa-germ and cholera-germ than between tissue-germ and pus-germ.

It may be then objected by the anti-contagionists that if there is merely this difference of conditions there is no need of supposing a propagation from person to person, for all in given areas are subject to like conditions, and the disease may be epidemic (the disease-wave falling upon the multitude) and yet not infectious (not propagated from one to another). The answer to this is first given by a glance at the map of the progress of cholera. It is seen that the disease does not exist in patches, nor in circles round given foci, but in lines—lines which follow the tracks of human intercourse. But the argument can be conveniently deferred till further evidence is brought to bear upon cholera poison considered as a germ.

It will be better to anticipate other considerations concerning the characters of the cholera germ by inquiring "Upon what part of the economy is it probable that the cholera producing molecules first manifested their effects?" The experience deduced from the late outbreak I quote from the Registrar-General's Report:—"The population of London probably inhaled a few cholera corpuscles floating in the open air, and more rising from polluted waters and from the sewers; but the quantity thus taken from the air would be insignificant in its effects in comparison with the quantities imbibed through the waters of the rivers or of ponds into which cholera dejections . . . had found their way, and had been mingled with sewage by the churning tides." I think no dispassionate inquirer can review the extant evidence without coming to the conclusion that the poison of cholera, whatever that may be, is chiefly engrafted into the system by the way of the alimentary canal. Whatever, therefore, the conditions which produced the first germ of cholera—whether it arose from the inhabitants of Eastern climes eating diseased rice, or whether it arose from their drinking water poisoned by their own dejections, or whatever its origin and the vehicle of its introduction—there is an amount of probability that it first entered the alimentary portion of the body.

We may next ask, "What do we know of the habitat of the cholera germ?" We have mentioned one condition, warmth. The next indicated by a preponderance of evidence is more precise—a soil containing sewage matters. If we accept the water theory of the propagation of cholera we must accept the sewage theory. A great agreement of testimony shows (*a*) direct evidence of impregnation of drinking water with sewage matters; (*b*) the intermixture in times of cholera of the discharges from infected patients with this sewage matter; (*c*) a great agreement in the evidence to show that persons who drink such contaminated water become affected with cholera. This establishes an *à priori* case, which is strengthened by (*d*); it is proved by many cases that those who wash the excrement-stained clothes of cholera patients are liable to take the disease. This evidence, however, has been still more completely strengthened by the observations of Pettenkofer, Thiersch, Sanderson, and others. Pettenkofer, after the most careful scrutiny of possible conditions and combinations of conditions, comes to the conclusion that the great egenda for the production of cholera, besides the existence of the specific germ, are porosity of soil and impregnation with sewage. In localities where a moist sewage-laden soil is nearest the surface is cholera most prevalent during an epidemic. The synthetic test has been applied first by Thiersch, secondly by Sanderson. They administered in minute amounts the alvine discharge of cholera patients to healthy mice. The result was the production in many cases of choleraic symptoms in the animals. The experiments which showed communication of the disease were made at a mean temperature of 56° F. At a temperature of 49° F. they failed. If we can accept with any definiteness the results of these inquiries we may deduce some further information concerning the cholera germ. According to these, as tersely summed up by Dr. Farr, "The fresh fluid the first day after exposure to the air is almost inert, on the second day it grows more active, on the third it is at its maximum of activity, is less and less active on the fourth and fifth, inert on the sixth day of transformation." It thus appears that the greater or less morbid power of the cholerad coincides with the varying phases of its development.

From the foregoing observations we may deduce the following as the necessary conditions for the activity of the cholera germ: (1) a soil containing sewage matters; (2) warmth; (3) moisture.

With these preliminaries we may glance at the present state of our knowledge as to its natural history. The first question we may be called on to discuss is this—

Is the cholera poison a species of urocystis?

It seems now to be probable that we in this country have done Professor Hallier an injustice. I think I am right in the idea that when the records of his labours on fungi as the prime causes of cholera first came to us, we considered his doctrine to be that the bodies of peculiar cyst-form, which he discovered to be peculiar to the alvine evacuations of those suffering from cholera, were the active agents in the production of the disease; that the relation of urocystis and cholera was one of direct cause and effect. It would seem unlikely that this urocystis, which is not abundant, and, though not minute, is with difficulty discovered, should be the widely-spread, rapidly multiplying, subtly working cholera poison. Hallier's critics, who have expressed their dissent from his views in no measured terms, have perhaps looked at his theory of cholera causation as I have just expressed it. Whether, however, this were Hallier's view at the outset of his inquiry, which he has subsequently modified, or whether his early views were misunderstood, it is certain that he does not now maintain the relation of urocystis and cholera poison to be one of cause and effect. The relation which he maintains should be expressed thus: not "urocystis is cholera poison," but "a germ in the progress of whose development urocystis is a characteristic stage, is cholera poison." We have taken the accident for the element. (See *Lancet*, Jan. 16, 1869.) Inasmuch, therefore, as the urocystis theory in the form expressed is no longer held, and as the rice theory which accompanied it is abandoned ("Professor Hallier has now abandoned his views as to the similarity if not identity of his cholera cysts and urocystis."—Report by Drs. Cunningham and Lewis, *Lancet*, January 9, 1869."), we may pass on to a second question—

Is the cholera poison a vibrio?

If we admit a resemblance between fermentation and zymosis, and if we believe in the observations made by M. Pasteur, we have *à priori* ground for answering the question in the affirmative. The ferment of butyric acid, for example, says M. Pasteur, is a vibrio. Supposing the cholerad were a vibrio, would it be possible adequately to explain its transmission from person to person by ponderable media and through vast bulks of water? Dr. Farr, in his Report (giving no adhesion, let it be remembered, to any theory declaring the cholera poison a vibrio), says:—"The habits of the vibrion, the velocity of its development, and its power of disorganizing other organic forms, are seen under the microscope. If vibrions constituted the cholera ferment, diffusion through water, and to some extent through sewers or air . . . would be perfectly intelligible. Two vibrions would become by fissiparity 4, 8, 16, and at the 100th generation, at this uninterrupted rate, 126,765,000,000,000,000,000,000; and as generations succeed each other by the hour, this accounts for the swarms in every drop of cholera fluid."—(Report, cit., p. lxvii.) Concerning the minuteness of these bodies, Pacini has declared that vibrional molecules are less than 1-25,000th of an inch in diameter. A cubic inch of water might contain millions of particles like these. These considerations are potent to explain many of the phenomena of cholera propagation. What, then, is the evidence of direct relation with the observed appearances in cholera itself? Hassall, in 1854, though he attributed no causative relation to them, detected myriads of vibrios in every sample of the rice-water discharges of cholera which he submitted to examination; he also found them in abundance upon the linen of patients affected with cholera.

Though these considerations seem to render probable the view that vibrios stand in some causative relation with cholera, there is another circumstance which militates against that view, and which at once negatives the absolute assertion that the vibrio is the efficient agent in producing cholera. This circumstance is, that vibrios are found in myriads throughout the natural world, and that they accompany fermentation and putrefaction under *all* conditions.

We may therefore pass on to inquire—

Is the cholera poison a molecule possessed of vital properties, yet so minute as to be undiscoverable by our powers of vision however aided?

It is well known that Dr. Beale has attributed the first elements, as well of the organized parts (living tissues) as of an organized whole (living organism), to a translucent material, possessed by what means science cannot trace, but which can only be expressed, as by the will of the Creator, with properties known as "vital." Dr. Beale does not pretend that this primordial matter, the origin of a living structure, shall be always detected. He has recognized this material as the first cause of zymotic disease, and has demonstrated it in vaccinia and in cattle plague. In applying the same views to cholera there is evidently a great resemblance between his own and those of Pacini and of Hallier. His germinal matter is the choleragenic molecule of Pacini, the micrococcus of Hallier. Hallier defines his term micrococcus "particles of plasma without any cell-wall."—(*Lancet*, January 16, 1869.)

By an examination of the evidence which we now possess concerning germs and their propagation, I think we may be able to explain some apparent contradictions, and reconcile the theories of observers which have seemed at first sight to have been conflicting. It seems to me that false conclusions would be rendered less possible if we could agree that it is impossible to state that any appearance described by the microscopist is a primordial form of matter.

Let us glance very briefly at the views held by observers as to the origin and development of organized bodies. If a solution in which spontaneous fermentation has not yet begun be examined under the microscope, besides the organic *débris* nothing can be discovered. Soon, however, appear granules, and afterwards vibrios. It follows that there existed before these vibrios evident to vision germs of vibrios which were not evident to vision. We must be careful not to assign to the objects which we see initiatory powers which belong to living particles which we do not see.

Another important fact is to be borne in mind—that fermentation is a process complex in regard to the various manifestations of life. It is not attended with the production of forms of a single kind, passing through definite stages and arriving at a definite maturity, but with the production of various bodies differing not only in degree but in kind. Dujardin discovered fifty species of infusoria during the putrefaction of a single substance. Moreover, the forms presented belong not only to the vegetable, but also to the animal world. Mitscherlich long ago propounded the doctrine that animalculæ were amongst the essential agents of fermentation. It is certain that the development of microzoa accompanies that of microphyta. It will be interesting to inquire whether this coexistence be an accident or an essential of the proliferation of germs. I do not know that this question has ever been imported into a discussion of the phenomena of zymosis.

M. Lemaire, "De l'Acide Phénique," &c., second edition, chapter II., investigating the action of carbolic acid upon germinating seeds, came to the conclusion that "infusoria are indispensable to germination." He makes the singular remark that "the seed is in some sense the foster-child (nourrisson) of infusoria." It cannot be said that his arguments (they are too long to reproduce here) are unanswerable, but they raise a question which deserves a careful investigation. If a vegetable sporule cannot germinate except in the presence of other organisms (and as some of these organisms partake undoubtedly of an animal nature, we must agree, unless we admit the paradox of a vegetable germ being capable of transformation into an animal germ, that germs of microzoa are present), it imports a postulate into the theory of fermentation which has scarcely been recognized.

According to the views of M. Pasteur there is for every kind of fermentation a distinct kind of organism which induces it. Vibrios are essential to butyric, mycoderms to acetic fermentation. To sustain the analogy with zymotic disease we must, if we accept his views on this point, agree that the organisms capable of inducing the various diseases are distinct and unvarying in kind. This doctrine, however, is not uncontested. Lemaire contends "that there does not exist a special ferment for each kind of fermentation, that the function of microzoa and microphyta is to bring back matters to a more simple state admitting of new combinations. Alcohol, acetic acid, and, no doubt other bodies, can be produced by means of microphyta; bacteria, vibrios spirillum, and monads; the presence of these minute organisms in such or such liquid is a question of relation; the composition of the liquid is the cause of their order of appearance." The observations of Prof.

Hallier seem to confirm this latter view : he states that certain fungi appear in distinct, definite, and unvarying forms, accordingly as they are cultivated in a soil rich in nitrogen or in a soil poor in nitrogen His micrococcus "on being introduced into a fluid capable of alcoholic fermentation becomes cryptococcus, corresponding with the bodies which are generally included under the vague term ' yeast cells. ' If, on the other hand, micrococcus be introduced into a fluid capable of sour fermentation they become arthrococcus, *i.e.*, they assume an elongated form and become one form of what are commonly termed bacteria."—(Report by Drs. Cunningham and Lewis, *Lancet*, January 16, 1869.) The nature of the fungus produced, therefore, depends upon the soil on which it is propagated; the penultimate form is the particle of plasma, the germinal matter ; the ultimate form, as I have before suggested, is beyond the powers of vision. The variations of development, according to habitat and surrounding circumstances, obtain an analogy in the case of these complex organisms—witness the "wanderings" of the trematode, the observations of Kückenmeister and others. The cysticercus of one animal if swallowed by an animal of another species becomes a tænia. The very nature and function of an organism becomes changed according to its habitat.

From the foregoing considerations, if we accept them as premises, we may conclude—

1. That any organized body detected in any circumstances of fermentation or of zymotic action cannot be logically determined as the efficient agent of a fermentation or of a disease. The presence of one form is only the index of others still more minute.
2. That it is probable that a concurrence of organized particles, having different properties and varying modes of development, may be necessary to zymotic proliferation.
3. That a germ which, under certain circumstances, produces certain effects, may, under a change of circumstances, produce other effects.

Considerations such as these at once refute the argument of those who state that there is no cholera poison because it cannot be demonstrated to vision. There is a time when the germ of everything which subsequently lives is invisible. It is hopeless to trace the actual origin of the cholera germ. The spec of plasma, so minute as to be invisible under certain circumstances, which were probably principally those of heightened temperature and a soil more than usually rich in the nitrogenized principles presented by the excrement of animals, developed into a new form and acquired new powers. These powers varied according to the phases of its development. Swallowed in drinking water by human beings the germs exercised a toxic power, varying in degree according, probably, to the number contained in the quantity swallowed, the period of development of the germs, the susceptibility of the individual subject to their influence, and the condition of the alimentary canal which became the soil upon which they were sown. Passing away from one individual mingled with the sewage matters, in which they found congenial conditions for their further propagation, they influenced others and others until some circumstances occurred to arrest their vitality, or to check their development below that stage in which their virulent powers are manifest; then the disease, the consequence of their influence, declined. I have next to trace the probable operation of these germs upon the internal economy.

(To be continued.)

THE INFLUENCE OF OCCUPATION ON THE HEALTH.

By E. Symes Thompson, M.D., F.R.C.P.,
Assistant-Physician to the Hospital for Consumption, &c., Brompton.

"The Influence of Occupations on the Health" formed the subject of the first of the recent course of lectures at Gresham College. After alluding to the evil effects of overcrowding and defective ventilation on the health of workpeople, who are packed together for hours in large manufactories, and pointing out the false economy of those masters who, disregarding their own best interests, call upon their hands to go through their daily occupation under circumstances which tend to enervate them, and render them less and less capable of doing the greatest amount of work in the least space of time, the lecturer asked how it came to pass that employers of labour should be allowed to take away the lives of tens and hundreds of men and women by carbonic acid, and the foul products of respiration, when it is contrary to law to poison one person with prussic acid or strychnine? The position of women and girls who, even more than men, are subjected to these fruitful sources of disease, viz., overcrowding, ill-ventilation, and long hours, was mentioned as one of peculiar hardship, and the Professor instanced as a case in point, the Luton and Dunstable straw-plaiting trade (see recent Report to Privy Council). Here it appears to be not unusual to keep girls twenty hours out of the twenty-four in a room the temperature of which frequently exceeds 70° Fahrenheit, with only about forty cubic feet of air space for each person. The lecturer passed on to notice the special forms of disease incident to certain trades, giving instances drawn from his own experience, and at the same time remarked that it was a subject of congratulation that the condition of nearly all classes was better now than in days gone by, for science had done much in the way of suggesting remedial and preventive measures. The ill effects on the workers in poisonous substances, *e.g.*, arsenic, mercury, lead, phosphorus, &c., are notorious, but the influence of minute particles of dust in originating diseases of the respiratory organs was not so generally recognized by the public. For this latter evil the use of respirators, and the "moustache movement," as a protection to potters, stonemasons, millers, &c., was referred to as a wide and ready adoption. The unhealthiness of tailors, shoemakers, and bakers, the Professor held to be traceable rather to the general evils mentioned above, than to anything specially detrimental in the callings themselves.

Dr. Thompson further enlarged upon the importance of bestowing more attention to the subject ; employers with the view of ameliorating the condition of their workpeople, and the employed in order that they may perform their daily work so as to be least exposed to the evils attendant on their pursuits ; and, secondly, with the object of finding the employment best suited to their capacity. On this latter point the Professor drew attention to the proficiency attained by female telegraphists, and in conclusion advocated emigration as the true remedy for overcrowding, remarking that the aversion to it on the part of the labouring classes sprang from ignorance of the realities of emigrant life.

ON ULCERATION OF THE RECTUM.

By Holmes Coote,
Surgeon to St. Bartholomew's Hospital.

The mucous membrane of the rectum and adjacent part of the colon may be the seat of diffused ulceration. In the museum of the hospital (Ser. xvi., No. 64) there is a specimen showing the "rectum of a girl twenty-five years old." Its mucous membrane is entirely removed for several inches above the anus, and above the ulcerated part it is slightly thickened. The muscular and other coats of the intestine are thicker and denser than is natural, but exhibit no morbid alteration of their tissue. An interesting case has been recorded by Mr. Wormald. A lady, about thirty years old, had been for three years subject to occasional attacks of obstinate constipation, which were generally followed by diarrhœa. Four months before her death the obstruction of the intestines became complete, and after this time she had no fæcal evacuation. The cause of obstruction was found to be a cherry stone, which had lodged above a stricture in the colon, and completely closed the canal. After death it was found that the canal of the descending colon was at one part suddenly reduced to a quarter of an inch in diameter. Its walls at this part were slightly thickened and indurated, and a narrow band passed across its canal, dividing into two small apertures the orifice by which the portions above and below the stricture communicate. The appearances are as if there had been an ulcer of the mucous membrane, the healing of which had been attended by contraction of the surrounding intestinal walls, and adhesion of a part of its opposite surfaces. Both above and below the structure the tissues appeared healthy, but the canal below was very small, while above it was enormously distended with fæces and burst about two inches from the stricture.

Many years ago I came across a rectum in the dissecting room of the hospital—nearly the whole mucous membrane had been removed by ulceration, and the surface was occupied by a firm thin cicatrix. We had no history with the case. Ulceration of the intestine is best treated by keeping the part in a state of complete rest. A case in point is related by Mr. Hilton (On Rest, p. 275) :—A married lady, aged thirty-six, suffered from constipation, with pain in passing her motions and some discharge of blood. Shortly the pain became more severe, and lasted many hours. She had difficulty in micturition and pain over the sacrum. She was directed to take "warm purgatives." Next she was treated for piles, but without any improvement in her symptoms. Mr. Hilton found the sphincter spasmodically constricted or tightened, and next passing his finger further into the bowel he gave pain by pressing upon the gut towards the sacrum, and on withdrawing the finger there was blood on it. By means of a small reflecting speculum an ulcer was seen, ovoid, but irregular in form, its margin a little thickened, with the longer axis placed vertically. It was about an inch and a quarter in length and three-quarters of an inch in width at its widest part. The lowest part of this ulcer was placed a full inch above the sphincter of the anus. She was ordered to rest in the recumbent position, good and oft-repeated fluid nourishment, to take if necessary confection of senna with bicarbonate of potash, and an opiate enema every night after the bowels had acted. At the expiration of a fortnight her condition was greatly improved, and in the course of a few months she completely recovered.

In other instances we must refer the ulceration to the influence of syphilitic infection. As regards treatment, no other principle should be observed than that of rest; and the more so because remedies such as iodide of potassium, &c., and others which often act so promptly on ulceration of the integument, lose much of their effect when employed in the treatment of similar ulceration within the rectum.

REPORT OF A CASE OF RIGID OS UTERI.—INCISION.

Under the care of Thomas Henry Sandiford,
A.B., M.D., M.Ch., Ex. Schol., &c.

Mrs. A., aged thirty-one, suffered, since the birth of her second child about six years ago, from prolapsus uteri. When I first examined her in February last, the uterus was completely down, and quite hard and dry. Having replaced it, I ordered a pessary to be worn during the day, also a mixture containing ferri and quiniæ citras, and tinct. calumbæ to be taken. Shortly after this she became pregnant, her youngest child being then five years old. On Saturday, Dec. 19th, labour commenced. Upon examination the os could be detected, completely closed, very far back, and so high up as to be reached only with difficulty. The cervex was very thin and spread over the head, so that there was no difficulty in diagnosing the presentation to be in the third position. The pains continued fairly during the night, but on Sunday morning began to fail, and ceased entirely during the day. I therefore gave her a draught containing twenty drops of tinct. opii, which procured four or five hours sleep. On awaking the pains returned, and continued moderately during the night.

Upon examination on Monday morning the os was found to be dilated so as barely to admit the finger, and felt exactly like an india-rubber ring. There was no "bag of the waters," and the lower segment of the uterus was extremely thin and tightly embraced the head. Labour continued during the day, and the usual remedies recommended by Dr. Churchill for rigid os were tried without the slightest success. It was now evident that the labour had virtually assumed the second stage; the pains began to decline, and on Tuesday the symptoms of powerless labour were rapidly setting in. I therefore came to the conclusion that there was nothing for it but incision of the os. Accordingly, I sent for my friend, Dr. Tuckey, Medical Officer of Bantry district, who, upon a careful examination of the case, agreed in my opinion. We therefore set about incising the os, which was a task not so easily performed as would appear at first. The presentation being in the third position, the forehead rested against the pubis, and from the labour having for some time been virtually in the second stage, the head pushing against the lower segment of the uterus, distended the anterior portion of the latter more than the posterior. The consequence was that the long axis of the uterus being moved from its normal position carried the unyielding os upwards and backwards almost to the promontory of the sacrum. The anterior and posterior lips having been cut, the forceps was with some difficulty got in, and the patient delivered of a full grown female child, which was born apparently dead, but on the application of the usual means quickly recovered. Both mother and child are now doing well, the latter having got on without a single bad symptom.

The cause of the rigidity in this case would seem to be an altered state of the uterus in consequence of being protruded (during the day) for more than five years. When first I saw it, it was covered with what resembled hardened cuticle. There was also a small ulcer about the size of a pin's head at the edge of the os.

The total absence of liquor amnii may also have had its share in preventing dilatation.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

ABSTRACT OF A CLINICAL LECTURE

DELIVERED BY

MR. HENRY LEE.

One of the most interesting clinical lectures at St. George's during the present season was delivered by Mr. Henry Lee. As it treats of a subject not often touched, and is at the present time of unusual importance, we give a full abstract, assured that our readers will be glad to have the matured views of this surgeon before them.

Mr. Lee opened by saying that the process of repair in arteries is effected by means of a deposit from the blood. A number of corpuscles, resembling the white corpuscles of the blood, adhere to the injured internal membrane; and connected with these, and probably formed by them, is a quantity of fibrin-like substance, which glues together for a time the divided edges of the internal membrane. This material is capable of becoming as much organized as the internal lining of the arteries; and when it does so, the repair is complete. But it may, and often does, happen that that material deposited does not become so organized. A great practical distinction is here drawn between those cases in which the material deposited remains a part of the lining-tissues, and those in which it does not. When it does become organized, it is used in the process of permanent repair; when it does not, it must sooner or later be removed in the current of the circulation. The material used in the process of repair in arteries is different from that used in the repair of serous membranes. The one is a deposit from the blood, the other is a secretion from a membrane. Mr. Lee then proceeded to state the views of others.

Hunter believed that the lining-membrane of an artery would secrete lymph like a serous membrane, and he believed that by keeping the two sides of an artery in apposition he could make them unite. He tried the experiment in the first case in which he tied the femoral artery for popliteal aneurism. He used four ligatures, so as only to compress the sides of the vessel for a considerable distance. Secondary hæmorrhage occurred. The patient ultimately recovered; but it is evident, from the details of the case as given by Sir E. Home, that union did not take place between the sides of the vessel as was expected. For a very evident reason this kind of union does not take place between the opposed sides of arteries. If it did, these tubes would be constantly liable to be obstructed.

It has nevertheless been maintained, both by physiologists and surgeons, that this kind of adhesive inflammation does take place in the interior of arteries. Gendrin even cites an experiment to prove it. He threw an irritating injection into an artery between two ligatures, and describes as the result which followed the inflammation produced, a plastic layer which lined the internal membrane, and ultimately filled up the cavity of the vessel.

It is next to be noted that Turner, Hodgson, and Travers all followed the idea of Hunter of the effusion of coagulating lymph from the lining-membrane of the blood-vessels and of the matter found in their canals as a secretion by the capillary vessels under inflammation.

Mr. Lee does not accept the idea that the material found in blood-vessels inflamed by disease or injury is produced as a secretion would be from an inflamed serous membrane, and he showed the importance of this at the present time, when the different modes by which hæmorrhage from arteries may be arrested occupies so much attention.

Some years ago Mr. Lee found by experiment that if the blood were carefully excluded from a blood-vessel, irritating substances might remain in contact with its lining-membrane for a very considerable time without any effusion of lymph taking place, but if the blood was allowed to enter the vessel, a deposit of white fibrin-like material took place. Afterwards he allowed an acu-pressure needle to remain in contact with the main artery in a donkey's leg for three whole days. At the expiration of that time there was no appearance whatever of lymph on the lining-membrane of the vessels. A case was lately in St. George's Hospital in which an acupressure needle was allowed to remain in contact with the femoral artery for three days, and in which no effusion of lymph took place on the lining-membrane of the vessel. Cases and experiments illustrating the same point might be reported in great number.

There are some tissues in the body which are non-vascular. They are nourished by imbibition from surrounding parts, rather than from any blood-vessels of their own. The cartilages of the joints belong to this class. When a joint is diseased, the synovial membrane may become red, and may secrete different fluids into its cavity; but the cartilage, as long as its structure is unimpaired, remains of its natural white colour. By degrees the synovial membrane may encroach upon the cartilage, or this may become altered in structure; and then, but not till then, will the ordinary products of inflammation be secreted from its surface.

The lining-membrane of the blood-vessels in like manner is a non-vascular tissue. It lives by imbibition; and as long as it retains its natural structure, it does not secrete the ordinary products of inflammation. When the lining-membrane is altered in structure, or when it is so far destroyed as to allow the vascular coats of the vessel to come into play, then the ordinary results of inflammation may be produced in its interior.

There was some time since in Oxford ward a case in which a pulsating tumour in the ham followed a stab with a knife; an acupressure needle was introduced, so as to compress the vessel leading to the pulsating tumour. This was not done with any view of producing adhesion of the sides of the compressed vessel. The object in view was to leave that part of the artery which was originally wounded by the knife at rest till the natural process of repair should take place. This is usually prevented in any case of aneurism by the constant impulse of the blood. The deposit which, if allowed to remain, would become organized, is displaced by pressure from within. Another layer is deposited in its place, and this again in its turn yields to the same force. Thus are formed the successive layers of fibrine found in an aneurismal sac. Each one of these is displaced as soon as formed, and no one is allowed to remain sufficiently long to accomplish the intention with which it was first deposited.

In the case alluded to above the acupressure needle prevented any impulse from being communicated to the newly-deposited fibrin, which therefore had time to become organized, and union by first intention took place.

Mr. Lee added that the observations made apply directly to the use of acupressure after amputation. This practice, he said, a very valuable one in itself, has, by the writers who have advocated its use, been spoken of as producing union of the opposed sides of arteries. Mere apposition, Sir James Simpson says, is sufficient to close the largest arteries. Others who have followed Sir James Simpson have stated very boldly that the coats of an artery, if kept together for a few days, will unite.

But Mr. Lee concluded, from what has already been stated, that union does not take place when an artery is compressed unless the pressure be continued sufficiently long to destroy the structure of the lining-membrane. The real repair, if the acupressure needle be removed before this is done, takes place at the cut extremity of the artery, and not at the point at which acupressure was applied. If the adhesion there be not sufficient, there is a risk that the impulse of the blood will remove the coagula, and that secondary hæmorrhage may take place. Mr. Lee shortly showed how intimately connected with this subject is the mode of arresting hæmorrhage by torsion, upon which much light has been thrown by Dr. Humphry and Mr. Bryant. When an artery is twisted, the same effect is produced upon its internal coats as if it were forcibly extended. Being more brittle than the outer coat, they are torn across, and have a tendency afterwards to curl up. If an artery, according to Mr. Bryant's plan, is twisted until something is felt to give, and then left, the internal coats will have become lacerated, and their edges will project into the interior of the vessel. The end of the artery which, if the torsion had been continued, would have been twisted off, is left as a kind of rude cork at the end of the tube. The blood then coagulates in contact with the lacerated internal coats. When these are deficient, the opposed sides of the external coat are brought in contact by the torsion; and if left at rest, the process of repair begins. Mr. Lee then referred to a case in which torsion was successful when applied to the femoral artery in a case that occurred by no means promising, and expressed an opinion that the process is more applicable to large than to small vessels.

◆

TETANUS TREATED WITH CALABAR BEAN.

Drs. Boslin and Curren (*Chicago Medical Journal*) have treated a case of acute traumatic tetanus of violent character with large doses of morphia and calabar bean. For a portion of the time, a grain and a half of morphia and three grains of the powered bean in glycerine were given every hour, with the manifest effect of quieting the patient and relieving the spasm. The patient recovered.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

CASE OF EXTRAVASATION OF URINE RESULTING FROM STRICTURE OF FORTY YEARS' STANDING.

UNDER MR. R. PERSSE WHITE'S CARE IN JERVIS STREET HOSPITAL.

(Reported by Mr. Francis Coyne.)

Peter Lane, æt. sixty-two, a coachsmith, of very intemperate habits, and much debilitated by a varicose ulcer on his leg, was admitted into Jervis Street Hospital, Oct. 26, 1868, suffering from retention of urine. Forty years ago he contracted gonorrhœa, and two years later symptoms of stricture came on, which he neglected, and after four years retention occurred. He was cured by Dr. Hutton, but after a time resuming his drinking habits the stricture returned, though it did not inconvenience him much for twenty years. His stream of urine then became very small, and he applied to Dr. Stapleton, who admitted him into this hospital, placed him under treatment, and dismissed him in a fortnight with the stricture fully dilated. After this he remained tolerably well for six years, until drinking hard one day and getting a wetting, retention again came on; he was treated in the country, and was able to resume his work on the following day, but the stricture still remained, and eleven months ago stillicidium supervened; since then, he says, he could not keep himself "dry" a minute. In 1865 he was admitted into this hospital bleeding from a varicose ulcer on his right leg. When leaving he was advised to give up his trade (at which he was obliged to stand constantly). He did not, the ulcer returned, and after eleven months it burst again. Since then he remained at home, until Sunday, the 25th, when, feeling stronger, he went by train "to see Howth." He says he drank only one glass of beer there during the day, and whilst waiting for the return train in the evening he felt a chill; this recurred in the train, and on his arrival home he experienced great difficulty in passing water, which came only in drops. These symptoms continuing during the night, he applied here next morning. Mr. Sheedy, the resident pupil, admitted him, and with some difficulty succeeded in introducing a No. 2 catheter into the bladder, and drew off a few ounces of high-coloured urine. This gave him some relief, but towards evening the rigors returned. Next day an unsuccessful attempt was made to introduce a catheter; he was treated with the warm bath and bromide of potassium, but in the evening the rigors came on again. On the following day the same efforts were made with a like result, the bladder being relieved by the constant dribbling away of the urine as before his admission, but he suffered from rigors each day, until the evening of the 30th, when the stillicidium and rigors ceased, and he felt a "stinging" pain in the perinæum. On the following day the perinæum was observed to be tense and discoloured, and he complained of pain in that situation; the urine was again dribbling away. On Monday, Nov. 2, Mr. White saw him for the first time. He had then passed a sleepless night, pulse 110, tongue dry, and coated with a thick brown fur, skin greasy and discoloured, complaining of severe pain in the perinæum, scrotum, and lower part of the abdomen over the bladder. On examination, the scrotum was found enormously enlarged and of a deep red colour, the penis infiltrated, greatly increased in size, and with a large black patch occupying the entire of its right side. Behind the scrotum was a tumour the size of a small orange, tense and purple in colour; the entire perinæum was in the same state. A free incision was immediately made into the posterior part of the scrotum, dividing completely the small tumour and the perinæum back to the stricture, giving exit to a quantity of fœtid pus and urine; then another incision about two inches in length was made into the side of the penis, dividing through the black patch down to the cellular tissue, which was of a dark green colour, sloughy, and full of urine, which actually flowed from it. A charcoal poultice was applied. He was ordered 12 ℥ wine, bark mixture, with carbonate of ammonia in effervescence, and 5 grs. of Dover's powder each night.

Nov. 3.—Greatly relieved; urine coming freely through the opening in the perinæum; pulse 104; general state much improved. It was found impossible to introduce a catheter, the entire of the anterior part of the urethra being in a state of slough; to continue same treatment.

Nov. 5.—Pulse 120; urine coming through wound in the side of the penis, the wound in the perinæum being closed by the slough; slept but little. A large portion of sloughy tissue was cut away, and a free communication established between the wounds in the perinæum and penis.

Nov. 6.—Much better; pulse 96; tongue moist and creamy; urine coming freely.

Nov. 9.—Going on favourably; rests better at night. A mass of slough was removed from the scrotum, and a large drainage tube passed from the upper to the lower wound, and retained there.

Nov. 12.—Rests well at night; urine comes freely through wound in perinæum. Can now retain his water for some time. Drainage tube removed, and with it a large slough, about the size of a man's fist, in appearance like a piece of rotten chamois, came away. The urethra is quite destroyed, from the fossa navicularis to an unknown depth in the inflamed scrotum.

Nov. 14.—Medicine discontinued; to have haust. rheia and pills of quinine, opium, and sulphate of iron.

Nov. 22.—Has gone on well up to this; wounds now quite clean, health much restored; can retain his water for a couple of hours; scrotum fast returning to its natural size; wound in the perinæum closing.

Dec. 7.—Wound in perinæum closed; urine flows from the anterior wound, in fact from the front of the scrotum; the penis healing rapidly; general health good.

Dec. 9.—A small-sized silver catheter was introduced into the bladder, and allowed to remain until the following day.

Dec. 11.—Introduced a No. 6 catheter, and left it in two hours.

Dec. 20.—A No. 8 metallic sound was introduced every second day since last report.

Jan. 9, 1869.—The original stricture is apparently quite cured; all the wounds perfectly healed; he can keep his water for three hours; sleeps well, and says he is in better health than he has been in for the last forty years. He left hospital to-day.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

The annual dinner of this society is to be held on Monday, March 8th, at the Albion Tavern, Dr. Richardson, President, will take the chair. This promises to be a large and genial gathering of the fellows of the society, both from London and the provinces. Mr. Peter Marshall is nominated as the future president. We trust that the enthusiasm and success which have attended the very numerous meetings of the society, under the presidency of Dr. Richardson, will come out well at the dinner, both to cheer him who leaves the presidential chair, and cordially to welcome him who next succeeds thereto.

◆

SURGICAL SOCIETY OF IRELAND.

At the meeting of the Society on Friday evening, the 22nd of January, in the Albert Hall, Royal College of Surgeons, Professor Macnamara, Vice-President of the College, in the chair, Mr. **Morgan** detailed the treatment adopted in his case of "Aneurism Cured by Compression," the circumstance of which will be found in the Society's proceedings published last week.

The patient was warmly clad in flannel—the limb wrapped in wadding, when the pain was severe. The parts were painted with T Aconite, which gave most relief, and T of iron in bitter infusion, and liq. morph. administered regularly. Nutritious diet, rest in bed with the shoulder in position, and a shot bag of from six to eight pounds applied over the tumour. This not only diminished pulsation, but relieved the pain. In very much this condition he remained, the collateral circulation amply sufficing to carry on the supply to the limb in its attenuated condition.

November 25, 1868.—The pain has now rather suddenly increased, paroxysmal in character, and extending down the arm and side for the first time, also very severely in the fingers; he grinds his teeth in agony; there is no abnormal heat, and the radial is now perceptible, like a knitting needle in size, the brachial not being so evident. The tumour is enlarging, and becoming more soft and distinct, especially below the clavicle, the wave of fluctuation, as it were, being easily felt by the fingers placed below and above the clavicle.

I now applied ice over the tumour, which diminished the pain very perceptibly.

Fœtid enema with T opii occasionally was administered, and gave relief temporarily. I thought it reasonable to give him a trial of the iodide of potassium treatment, which was administered three times daily, in fifteen-grain doses.

The pain was described by the patient himself as "enormous," and unendurable, and during the paroxysms he used to ask most piteously to have something immediate done for him.

On the 28th of November, seeing the enlargement gradually progressing, I determined on trying carefully-applied manipulation, in presence of my colleagues. I tried by the fingers, and, by putting the body in the most favourable supposed condition, to detach, if possible, a plug from the tumour, but unsuccessfully, and the attempt was carried out as vigorously as was thought at all consistent considering the size of the tumour.

From this report (28th of November) to the 14th of December, the history was without much change; the iodide of potassium treatment was continued till the 13th, when stopped, as the patient was thinning, and was suffering from perspirations, apparently caused by the iodide of potassium, as it intermitted with the omission of the treatment, and set in when the influence of the medicine showed itself by coryza and iodinic symptoms about four days after its first administration. The pulse at the wrist is perceptibly increased, though still very small, and about the size of a surgeon's probe, the brachial hardly more sore, and the axillary even less perceptible.

The temperature in both arms about the same, though the affected was so sensitive to cold that it was kept wrapped up in wadding.

Seeing the progress in size of the tumour, which was rapidly increasing below the clavicle, and becoming soft, and that the patient could not longer endure the paroxysmal intense pain, that palliative measures, and all that could well be done was done, in order to alleviate his sufferings or cure the disease, I proposed to him the possible chance of prolonging life by an operation, which, though by no means promising, yet, might arrest the fatal changes that were taking place, it was determined to cut down on the artery at its origin, and then, on inspection, decide on what course to pursue as to ligature, and whether apply a temporary or permanent one.

On the 17th of December, the patient being chloroformed, and put in the best position for operation, I made a ⅃ incision over the origin of the sterno-mastoid muscle, which was there divided, as were the sterno-hyoid and thyroid, the latter not to its full extent, considerable difficulty was experienced in carrying out these stages, owing to the density and matting together of the tissues, no doubt caused by the long continuance of the disease and the peculiar position in which the arm was kept during several months. The phrenic nerve coursing down on the scalenus muscle was seen, but the vagus was not, as was shown by the *post-mortem* examination to be impossible, owing to its adherence to the vessel and the condensed fascia, and for the same reason, the internal jugular was but faintly perceptible. The arteria innominata could be felt, but corresponding to the subclavian in its natural position. No vessel could be found between the finger and the cone of the pleura, though anxiously examined, for the vessel corresponding to the carotid in origin seemed to supply the tumour, as, when experimentally grasped, the pulsation in the sac was reduced almost to nil, a slight thrill only being perceptible, while the size of the sac was immediately reduced, and the pulsation in the vessels of the head and face was *not* arrested, or any cerebral disturbance shown, allowing for the fact that from the long continuance of the disease, and the obliteration of the axillary, brachial, radial, and ulnar arteries, the anastomosing vessels had been immensely augmented, and were quite sufficient to carry on the supply between the head and face and the upper extremity. Finding, also, no vessels between the finger and pleura, taking into consideration the occurrence of anatomical irregularities of origin and course in the artery, the remarkable command over the tumour by compression of the artery, together with the displacement caused by the size and adherence of the tumour to the parts around, it was determined, after consultation with my colleagues and several members of the profession, surgeons of eminence, present, to ligature this vessel in preference to isolating arteria innominata, which was accordingly done, pressing down the ligature well on the artery. The pulsation in the sac was immediately all but arrested; a slight pulsation could still be felt, not more, or even as much as might be expected from the enlarged collateral vessels; the parts were very deep; the space between the trachea on the inside and the encroaching tumour on the outside was limited, but the wound was then closed by sutures. The patient recovered from the immediate effects of the operation in about half-an-hour, and passed the remainder of the day without a bad symptom. On the succeeding Sunday he suffered from a partial attack of syncope, without any apparent cause, and for some hours I was much alarmed for his safety. However, from this state he progressed favourably.

On the fifth day after the operation the pulsation of the right temporal artery first ceased, and on the next day the facial of the same side and the other branches of the carotid directly after, indicating that obliteration of the main trunk was gradually taking place, by ligature, and that the subclavian in its first stage must have been obliterated, the collateral vessels being the source of supply to the sac, which had now become more solid, and diminished in size, and was in hopes that, notwithstanding the difficulties of the operation, the perplexing conditions of the parts, and the circulating channels, when finally exposed, that a gradual occlusion by clot was taking place.

Everything went on favourably till Christmas day. About twelve o'clock in the forenoon the patient appeared somewhat oppressed and hurried in his respiration, but had otherwise no complaint; the percussion sounds over the front and sides of the chest were clear. I did not examine the posterior aspect, as I feared changing his position. About two o'clock of that day, however, he suddenly became collapsed, sphincters relaxed, and some welling up hæmorrhage appeared at the wound. Having hastily summoned my *confrères*, I opened the wound, in hopes of being able to ascertain and arrest the bleeding point; but nothing could be seen to warrant interference further, as it was evident the patient was dying, not from loss of blood, but of dyspnœa and exhaustion.

The patient died in about one hour from the first approach of the urgent symptoms, being eight days and some hours after the operation.

Mr. **Barton** said the previous history of the patient before he came under Mr. Morgan's care, appeared to him to be of great practical interest as regards this serious disease of aneurism of the subclavian artery. The case came under his observation in the middle of January last. The symptoms presented at the time were such as to lead to the conclusion that there was an aneurism of the subclavian artery of the size of a small egg. The aneurism was pervious and filled with fluid blood. The sac was quickly emptied and quickly filled again, and they could feel the thrill of the fluid blood passing into it when the pressure was removed. He had the patient under observation with a view of putting to the test different plans of treatment. Feeling that these ought to be tried thoroughly and satisfactorily before the last resource of an almost hopeless operation was attempted, he placed him in the Convalescent Home at Blackrock. He tried, first of all, perfect rest and a recumbent posture. Other plans were subsequently adopted, but each plan left the tumour where it began, and there was no perceptible improvement. While explaining the object of the treatment on one occasion, the patient, who was an intelligent man remarked that he could stop the pulsation at will; that he had tried various positions, and found that by putting his hand in a forced position round his neck he could stop the pulsation. Taking the hint he (Mr. Barton) tested the matter, and, on the most careful examination, satisfied himself that the pulsation in the sac was controlled by that manœuvre. The man said he could not bear the position for any length of time, but if it were thought it would do him good he would try. He told him that to stop the pulsation was most important; and, thus stimulated, he persevered in trying it for twenty-four hours. His arm was kept rigidly in that position, although he endured great torture. On the next day there was a decided improvement. When the arm was let down the pulsation was decidedly less, and there was a manifest hardening of the sac. This was encouraging. The arm was again placed in the peculiar position with the hand round the neck, and he bore the pain with better hope, and for the three following days he bore it almost continuously. After this the pain diminished. A flannel bandage was placed the whole way up the arm, which seemed to give him some ease. At the end of three days pulsation had almost entirely ceased in the sac. First the bruit ceased entirely, and then the signs of pulsation diminished very much. It could be faintly felt at times, but at other times it quite disappeared. This plan was persevered in for the next ten days at intervals. He was allowed to take down his arm for an hour at a time, but it was kept up with great care, and the result was that on the 21st of March the pulsation had totally ceased in the sac when the limb was placed at his side, and when sitting up in bed. The pulsation in the artery below the sac had ceased long before this, and coincident with the stoppage of pulsation in the sac, the circulation in the lateral arteries sensibly increased. He hoped the man would be cured. However, unfortunately, he felt himself quite well. He left the house, contrary to directions, went down to the Rock road to see the procession of the Prince of Wales's entry into Dublin. He supposed he cheered. He had some drink, and came back to the Home, and next day the artery was pulsating again. It could not be controlled by the change of position, and after that, his history was increase of pulsation, and of pain and diminution of strength, until at last the pain became so excruciating that it appeared to him (Mr. Barton) that operative proceedings became necessary. At the same time, when the man entered Mercer's Hospital, he looked upon his case as hopeless.

Dr. **Darby** expressed the obligation which he and other members of the Society were under to Mr. Morgan for bringing that interesting case under their notice.

The **Chairman** said that if there was one subject more than another on which Irish surgery ought to build itself, it was in the treatment of aneurism, whether by the scalpel or the Irish mode of compression. They had reason to feel proud of the advances which had been made in the treatment of aneurism, he might say, within the walls of that Society. He recently had an interesting conversation with one of the most eminent surgeons in London, which turned on the treatment of aneurism by compression; and, so far as his humble abilities were concerned, they might be sure he did not allow the question to be begged in his hands. The English surgeon wound up the matter in talking of the want of success in English hands of the treatment of aneurism by compression, by observing that we seemed to understand the thing better in Ireland. And there could be no doubt about it. There had been success in Dublin hospitals in the use of this method, while there had been comparative failure in London. He attributed this to the determination of the Irish surgeons to carry out the treatment to a successful issue; not to be easily discouraged, but to persevere vigorously even under the most unpromising circumstances. He fancied that if an English surgeon had this case of Mr. Morgan's he would not have persevered as that gentleman had done in the use of compression, but would have had recourse to the scalpel. Mr. Morgan alluded to the recurrence of pulsation in the vessel. Now, he (the Chairman) had had an opportunity of pointing out to the most distinguished surgeon in England the results of the treatment of aneurism by ligature and compression, which were to be found in the Museum of the Irish College of Surgeons. That gentleman did not know the permeability which the artery subsequently acquired after being compressed; but in the Museum they would see some interesting preparations, removed years after the cure of the patient, in which that peculiar feature was illustrated.

Friday, February 5.

Present.—Messrs. Corley, Bookey, Minchin, Murdock, Willis, Swan, Buchanan, Lalor, Morgan, T. E. Beatty, Churchill, jun., Fennelly, Kelly, Purcell, Robert Moore, C. F. Moore, W. Stoker, Leech, McDonnell, Stewart, White, Ward, Mapother, Jameson, Roe, Butler, Stoney, Jacob, Speedy, McClean, jun., Anderson, Hepburn, Leney, O'Grady, Grimshaw, F. T. Porter, J. Kirkpatrick, Shannon, J. S. Hughes, Stokes, jun., B. T. M'Dowell, Bevan, H. G. Croly, E. Hamilton, Bennett, and Ziemssen, Aix-la-Chapelle.

SYPHILITIC ULCERATION OF THE URETHRA.

Mr. **Morgan** exhibited a morbid specimen illustrating ulceration of the urethra in a female. He obtained it within the last ten days, and the preparation now before them would show what had taken place. The bladder was opened, and he had left the symphisis pubis. They would observe a large hiatus that corresponded to the circumference of the bladder. The urethra was taken away by the chronic ulceration as completely as if it were removed with a knife. There was a chronic sore that affected the mucous membranes; there (exhibited the drawing) was one with ulceration of the urethra; there (exhibited the drawing) was another with the same thing attacking the mucous surface of the labia, and the mucous membranes of the rectum itself; and a third (exhibited the drawing) representing thick hard cartilaginous edges, completely insensible and with a smooth surface. These ulcers healed by a process of skinning over rather than by a process of granulation. This peculiar form of ulcer appeared, so far as his observation enabled him to judge, to attack the urethra specially, and never to stop until it eats into the orifice of the bladder. He also exhibited the skull of a woman, which showed signs of syphilitic disease. She got syphilis two years and a half ago. She had bubo on one side only. She never got mercury in any form, and was always treated in the Lock Hospital. After the space of two years she began to get this disease of the bones of the head, which was confined to the external table. Thus, she had large severe secondary ulcers, and necrosis of the bones of the head and of the acromion process. This woman died of erysipelas.

CASE OF DEPRAVED APPETITE.

Mr. **Frank Thorpe Porter** addressed the Chairman as follows:—

Mr. President,—The case that I have the honour to lay before the Society this evening presents not a few points of interest, and it is the type of a class of cases which cause no small amount of anxiety and trouble.

On the 6th of January I was requested to see a little girl, aged ten years, the daughter of a small farmer, residing near Swords, where I had been doing duty during the short illness of my friend, Dr. Davys. I was informed that the patient was suffering from severe sudden pain in the stomach and dry vomiting. On my arrival, I found the abdomen very much distended, tympanitic, and tender on pressure; the tongue was furred and had sordes upon it; the pulse 190; the countenance was anxious and expressive of severe pain and impending dissolution. The bowels were obstinately constipated, and had been so for several weeks. There were frequent attacks of dry vomiting, and the stomach would not retain food of any kind for a considerable time. The legs were flexed, and there was a peculiar death-like odour off the person. The urine was scanty, high-coloured, and offensive in odour. Upon minute inquiry, I ascertained that the appetite had been depraved, and that the patient had been habitually eating quantities of cinders for four consecutive years. I ordered anodyne fomentations, and an aperient draught, which the stomach rejected. I then had recourse to an enema, which was given under my directions by the intelligent midwife of the district. Much difficulty was experienced in the introduction of the tube, which was indented by the sphincter of the rectum, which kept up a pressure almost equal to that of a fœtal head when on the perinæum. After some gentle but persevering efforts the tube was introduced, and the enema caused the expulsion of quantities of scybala and cinders. The abdominal pain soon subsided, and also the swelling. The stomach was enabled to retain food, and the pulse fell gradually to the natural standard. In a week's time the child regained strength and was able to walk out and take exercise. A wish not to intrude too much on the valuable time of those whom I have the honour to address, and a desire to leave room for discussion, prevent me from dwelling too long on this case; but before I conclude I would wish to remark, that I made the most minute inquiry as to the existence of worms, hysteria, and insanity, and that I failed to discover any tendency to such affections; I am therefore at a loss to account for the existence of depraved appetite for so long a period as four years. The subject of depraved appetite has not received proper attention. In this case symptoms set in which might be mistaken for those of hernia or enteritis. I have known many cases in which life has been lost owing to organic disease consequent on malnutrition produced by the same cause.

A METHOD OF FACILITATING THE REMOVAL OF THE STARCH BANDAGE, ALSO APPLICABLE TO BANDAGES PREPARED WITH WHITE OF EGG, GLUE, &C.

Mr. **Charles Moore** read as follows:—

Every surgeon is well aware of the difficulty of cutting starched bandage with a pliers or a scissors, and we can all the more readily understand this, when we call to mind that it was of layers of linen the coat of mail of the ancient Roman soldier was made. The mischief apt to attend the removal of the starched bandage in the usual way is well seen by the injunction of an eminent modern surgeon, who advises that the cutting should be done over a muscle, in order that the skin over the bones should not be injured.

Having invariably encountered much difficulty in cutting starched bandages with Baron Seutin's pliers, I was led to try to use tin, hammered so as to resemble miniature metal spouting, rather shallower than a grooved director, and rather more than double as wide.

The form and size of the piece of "starched bandage director," as I propose to call it, which I would submit to your notice (exhibited a piece of the director), I have found to answer remarkably well.

It is hardly necessary to say that the length of the director must be adapted to the part to which it is applied: thus, one piece, or two short pieces, may be required for the foot and ankle, or for the hand and wrist, one for the leg, another for the knee, and one or two for the thigh. In the same way, the number for the arm and forearm may vary according to the position required, the nature of the injury, or the slightness or stoutness of the individual.

I have applied the director thus:—Having enveloped the injured limb in a sufficiently thick layer of cotton wadding, and placed suitably formed splints of pasteboard moistened in the starch solution over the cotton, I lay the director upon this (generally upon the front aspect of the limb), taking care to adapt its pieces to the shape of the injured part, so that the starched roller, which is then to be applied over all, may be cut with the greatest facility, and freedom from danger of the knife slipping out of the groove of the director.

It is hardly necessary to say that care must be used to prevent such an accident, at the same time it would only be by very considerable inattention that such an event could happen.

The director rather adds to the support of the limb during the drying of the starch bandage.

When procurable, I have in most instances rubbed some plaster of Paris into the starched bandage, as it contributes much to hasten its drying, and adds to its strength.

In applying the director, as I have endeavoured to point out, I have not found any inconvenience arise to the patient from its presence in the appliance, and it most materially facilitates the removal of the case formed by the bandage, pasteboard, &c., for readjustment, when the progress or state of the injury demands it. This end is not so well attained by placing a tape under the starched bandage when applying it, as a guide for the scissors or the knife, as has been recommended by some.

The director may be used in conjunction with fixed bandage, made of French glue, as proposed by Dr. Hamon, and recommended by Dr. Campbell de Morgan, and with most other materials used for a like purpose.

[Mr. Yeates, of Grafton street, has undertaken to manufacture the "starched bandage director."]

The **Chairman** remarked that he had found Seutin's scissors a most unsatisfactory instrument for removing a starch bandage, and whether Mr. Moore's method was easier and more effectual, was a practical question for surgeons to decide. Latterly, he (the Chairman) had removed starched bandages by the ordinary silver director, which he slipped up between the skin and the bandage, and then he slit the bandage up with his knife. Whether Mr. Moore's plan would contribute to the solution of what had been found a difficulty it was for the profession to decide.

OBSCURE ANEURISM IN THE SUBCLAVIEA REGION TREATED BY LIGATURE.

Mr. **Morgan** brought under the notice of the Society a case in which he had effected a cure of aneurism by compression, having used a double method of compression which was not often practised. The patient was a spare thin man, and very anæmic. He was a bookbinder or bookmaker by trade, and was confined from morning till evening, working twelve hours in the day; he was otherwise healthy. He had syphilis two years before, and ascribed the aneurism in the popliteal space to an accident. He jumped down two flights of stairs to save a person who had become entangled in a machine, and immediately felt as if something had given way, and experienced a severe pain in the ham. On the 1st of May, 1868, he first noticed the tumour, the accident having taken place three weeks previously. He came under his (Mr. Morgan's) care on the 4th of May, and then had a tumour in the popliteal space equal to the size of a hen egg. It had the usual centrifugal pulsation and other appearances, which left no doubt that the man was the subject of an aneurism in the popliteal space. He was taken into hospital on the 6th of May. The leg was bandaged with flannel and kept in an elevated position for four days, and a shot bag of 5lbs. weight was placed on the femoral artery. The collateral vessels began to enlarge; the temperature of the limb was equal to that at the opposite side, and he then thought he might try digital compression. Accordingly he got a series of students who kept up the digital compression for twenty-four hours. At the end of that time the pulsation still continued. On the 10th of May he put on one of Read's compressors at the point where the artery entered the thigh. At first it gave the man some annoyance, but after some time he found he could bear it tolerably well; but the skin beginning to fray it was found necessary to take it off, and substitute one of Carte's compressors. All this time the man had good nourishing diet with very little fluids. On the 15th of May he again tried digital compression, and after using it for twenty-four hours he manipulated the tumour with a view of detaching a portion of fibrin, but without success. On the 24th of May he applied Carte's apparatus, but the patient did not like it, and preferred Read's, which, however, could not be used, owing to the fraying of the skin. He now expressed a wish to go home, to which he (Mr. Morgan) did not object, as he thought the change of air would do him good. The case had now been under treatment for twenty-six days. He was re-admitted on the 11th of June, ten days afterwards. The tumour was considerably larger, but a slight consolidation had taken place round it, and the collateral circulation was larger. On the 22nd of June it occurred to him to try the double compressor. He accordingly put on Read's apparatus at the upper part of the thigh, and then applied a compress low down on Hunter's canal, enclosing a still stream between the two. After two days the aneurism became more solid, and at the end of four days the pulsation had ceased altogether. This condition was preceded by the formation of a hard chord between the two compressors, and after that the tumour became more solid. At the end of four days the consolidation had very nearly completely taken place. On the 24th of June the parts were thoroughly indurated; the sac had become quite hard and firm, and he was discharged cured. He examined the man on the 15th of September, and found the artery could be felt. He examined him a few days ago, and found the artery obliterated, although not so much as before; but the aneurism was cured, and the man was able to use the limb efficiently. Mr. Morgan proceeded to say that the President of the College had recently introduced an artery compressor, but he (Mr. Morgan) had contrived a little instrument, which he thought was superior in some respects. Mr. Porter's compressor might have this disadvantage: that as it descended downwards there was an open space in which swollen tissue might possibly become entangled, and in drawing it up the same result might happen. With the instrument which he suggested this danger would be avoided.

DISLOCATION IN A CHILD.

Mr. **Fleming** exhibited a drawing of a dislocation of the humerus of a rare form in a child, caused by a fall, the child having an infant in her arms.

(To be continued.)

◆

ENORMOUS SPLEEN.

A **diseased** spleen has been sent to the Museum of Toland Medical College, weighing between nine and ten pounds when taken from the body. The patient had leucocythæmia prior to death. The organ was adherent to the diaphragm, the abdominal walls, and the left lobe of the liver.—*Pacific Medical and Surgical Journal.*

NOTICE TO SUBSCRIBERS.—Subscriptions for the year ending Dec. 31st, 1868, are now due. Subscribers resident in England will greatly oblige by forwarding the usual amount, 22s. 6d., either by cheque or P.O.O., made payable to A. A. Tindall, 20 King William street, Strand, London.

Subscriptions in Ireland to be sent to 8 Lincoln place, Dublin, and in Scotland, to Maclachlan and Stewart, South Bridge, Edinburgh.

Advance subscriptions, 21s. 8d. post free per annum, for the current year, can also be paid as above.

REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR *is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price 5d. Stamped 6d.*

By Post to Annual Subscribers, £1 2 6
„ *If paid in advance,* 1 1 8

⁂ Post-Office Orders and Cheques to be drawn in favour of
A. A. TINDALL, 20, King William-street, Strand, London,
„ 8, Lincoln-place, Dublin,
MACLACHLAN & STEWART, South Bridge, Edinburgh.

Sole Agents for the United States.

EDUCATIONAL REFORM.—No. X.

THE MEDICAL CURRICULUM.

So thoroughly are we convinced that the Licensing Corporations should at once lighten the amount of compulsory attendance exacted in their regulations, that our last article was chiefly devoted to the enforcement of this duty. A complete revision of the whole curriculum must necessarily be a work of time, and, not improbably, in the hands of a deliberative body like the Medical Council, a work of years. Their first committee only is now sitting. That committee will submit a Report. That Report will be discussed, amended, and referred back to the committee. The committee will return the Report in a form for circulation among the Licensing Corporations, which will be requested to express their opinions for the next meeting. At the next meeting these opinions will be referred to another committee for digestion, selection, and tabulation. The tabulated digest will be read at the Council and entered on the minutes. The Council will resolve itself into a committee on education, to reconsider the Report of the committee of the previous year. Into the Report of the committee of the previous year alterations, verbal or substantial, will be introduced; or out of the Report of the previous year suggestions too rational and too subversive of present usage for the Licensing Corporations to adopt will be studiously eliminated. These eliminations will not be effected without varieties of vituperation bandied round the Council-table. The Council-table will be a "chaos of thought and passion, all confused;" calling for exhortations to order from the President, who will point out to the reporters that this ornamental portion of the debate has no particular bearing upon the subject, and need not encumber the pages of the Press. The Press, well aware of the proclivities of the Council, will already have instructed the reporters to omit the habitual and annual interchange of compliment and courtesy. The interchange of courtesy will "separate chief friends" till the next year, when there will be an affecting reconciliation, previously to the third consideration of the recommendations, which, meanwhile, have been again sent to all the bodies specified in Schedule A, and again been honoured or dishonoured by those bodies. The answers of those bodies will once more be tabulated by a committee, and it will be found that one or more important Colleges still decline adhesion. The letters of the Colleges declining adhesion will be entered on the minutes, and after the letters will arise a discussion about the powers of the Council under the Medical Act, in the course of which one member will urge an appeal to the Privy Council, a second member will declare an appeal to the Privy Council useless, a third member will say that nothing can be done, a fourth member—like a Greek Chorus after a murder—will affirm solemnly that something ought to be done, a fifth member will consider the case peculiar, a sixth member will abuse the Medical Act and utter a magniloquent exhortation for the Council to throw itself into the arms of the profession, a seventh member will abuse the Colleges which have made the Council ridiculous, an eighth member will urge an amendment of the Medical Act, a ninth member will point out that he always knew it would come to this, a tenth will request the President to say something. The President will state the case, and give way to the eleventh member, who has to make a proposition that the recommendations and the answers of the Licensing Bodies be referred to a committee to report at the next annual meeting, a twelfth will eagerly second the motion, a general chorus of approbation will ratify the brilliancy of the suggestion, attitudes of defiance will be abandoned, smiles will sit on the noble countenances which had been grim with scowls, the appeal to the profession will be postponed *sine die,* the amendment of the Medical Act will be put into a private pigeon-hole, and the Council will blandly pass out of disorder to the order of the day. This is a fair deduction from past experience, and therefore the prospect of a comprehensive amendment of our educational arrangements being carried very speedily into effect is not such as to make us indifferent to the partial improvements which we have advocated. But even if an entirely new set of regulations were likely to be issued at a date less distant, we could not admit the circumstance as a plea for delay in the application of common sense to curricula already existing and in full operation. We ourselves can never feel that the desired goal has been reached until a single set of regulations issued by the Medical Council for an uniform set of examinations for a minimum qualification to practise *all* branches of the medical profession has been obtained, and all partial and fragmentary diplomas have died the death. But whether far from this our object or near to it, we are exceedingly anxious to see the present system improved by the adoption of such easy and necessary alterations as the remission of attendance on second courses of lectures, and attendance in the wards before the first examinations have been passed. If the examining bodies care to go beyond these two cardinal points let them simplify their schedules, and let them adopt regulations which shall compel each student before he comes up for examination to show that he has watched the progress of cases, and to produce notes of his own whose genuineness has been certified by the chief authority at his place of study. Let them, moreover, cease to require attendance on botanical lectures and lectures on physics and elementary chemistry. A knowledge of these subjects is necessary, and should be demanded, but why should students be compelled to gain their knowledge of them by lecture unless they are naturally attracted to the lecture-room? All three can be learnt in the country without a professor, by the aid of text-books, observation, and local museums; and, if further assistance be necessary, the help of a friend or the help of a tutor. But if the lecture-room be inevitable, why should the lectures on these subjects be mixed up with the acquirement of the knowledge of the human body at the hospital and its medical school? No valid argument has ever been uttered for this illogical arrangement. Therefore we say to each Corporation—" Look to your own curricula and amend them. The amendments can be effected without any imitation of the Circumlocution Office, and will place you in a proper position at the Medical Council as a leader of improvement and not a drag upon it. Make a virtue of necessity, and while we are waiting for that perfect work towards which Associations, Reformers, and the Medical Council are gradually converging, give us a few instalments of improvement by the adoption of a better sequence and classification of subjects, and by the removal of that excess of compulsion which makes compulsion at once odious, ridiculous, and futile."

UNIVERSITY COLLEGE HOSPITAL.

In our article on Dr. Parkes's Scheme of Medical Tuition, we expressed ourselves strongly against propositions which would involve a diminution of the amount of remuneration to medical teachers, admitted, as it already is, to be inadequate in numerous instances. We also felt it our duty to criticize the public surrender of fees for clinical instruction made by the medical officers of University College Hospital for the purpose of assisting that institution in its chronic deficiency of income. In doing this, an incidental allusion was introduced reflecting on the surgical practice of the Hospital, and to the terms used therein reasonable exception has been taken. Hence we are desirous to reduce our observations to the limits of the strictest accuracy, as an act of justice to the staff of the Hospital; and we can make the necessary corrections with the greater cheerfulness because our words happened to convey more than they were intended to express. The passage ran thus:—" At that Hospital, under the impulse of the most benevolent feelings, the medical officers surrender their fees to prop up a small institution which is always in debt, and which only gets a fair supply of surgical cases when a house tumbles down or an unlooked-for railway accident occurs in the immediate neighbourhood." The employment of the word "cases" was an accidental error, as some of our readers may have inferred from the context. We were really alluding to those forms of injury which necessitate admission of patients into the wards; and we never doubted that cases of disease were attracted by the repute of the surgeons. If this alteration be made, the deterioration of the surgical practice of the Hospital will be reduced to much narrower bounds than the literal construction of our words implies. If we were writing the article over again we should omit the reference to the surgical practice of the Hospital partly because it assumed too picturesque a shape, and partly because it had no immediate connection with the principle against which we were protesting. How far even in its modified form our statement diverges from fact may be judged from the precise information which we have been at some pains to secure.

About the main facts of the first part of our paragraph there is no dispute. The Hospital, we are sorry to say, is in debt, and has been so for several years. We do not know the exact amount of the liabilities, but, according to the Report dated 1868, they amounted in 1867 to £7,425 16s. 3d., a sum less by £2,180 than at the corresponding period in 1866. To assist the Hospital in its need the medical staff surrender their fees for clinical instruction, and have done so from the time of its foundation. According to the *Lancet* (Feb. 29, 1868), the benefit to the funds has amounted to £1,500 a year, or, in other words, to £70,000 in thirty years.

In this Hospital there are 150 beds, of which 66 are medical, and 84 surgical. Of the 84 surgical beds 18 are devoted exclusively to disease, and 66 indiscriminately to injury and disease. During the months of January, February, and March, 1868, the following injuries were admitted into the wards:—

Simple fracture of lower extremity	31
Compound fractures and dislocations	13
Wounds	19
Concussion of brain and spine	8
Wounds of arteries	3
Strangulated hernia	7
Burns	5

These facts are given on the best authority, and we suppose that they may be taken as a fair average example of the cases of injury admitted into the Hospital. To make the statement complete, we subjoin the surgical diseases admitted during the same period:—

General syphilis	12
Stone in bladder	11
Tumours	27
Stricture	16
Ulcers	8
Joint diseases	12
Diseased testes	4
Aneurism	3
Diffused cellular inflammation and abscess	16
Disease of bones	5

It is right that we should add that as many cases as possible are treated as out-patients in consequence of the limited ward accommodation.

To give a just estimate of the practice of the Hospital, it must be taken in connection with the number of pupils. The average yearly entries number about fifty. University College takes the third place among the metropolitan Schools. That this Hospital should have one of the largest Schools is due to several causes.—1st. To the liberal educational arrangements at the College; the excellence of the accommodation; the spaciousness of the museum dissecting room and laboratories; the valuable scholarships; and the eminence of the teachers. 2nd. To an advantageous and agreeable situation. 3rd. To the prestige of the College, which has a long roll of distinctions gained by its alumni in competitive examinations. 4th. To the admirable nature of the clinical system and mode of instruction; and lastly, to the high reputation of the medical and surgical officers of the Hospital. We believe that the staff sets an example of utilisation of material which larger Hospitals would find it their interest to imitate, and we shall have much pleasure in hearing that the Hospital is free from debt, and can relinquish the claim which usage has given it to those fees which should be distributed among the professors who bear the heat and burden of clinical instruction.

◆

THE FUTURE OF PHARMACY IN IRELAND.

It is announced in the *Pharmaceutical Journal*, on the authority of Dr. Leet, the representative in the General Medical Council of the Apothecaries' Hall of Ireland, that "the Company have given their consent to a Bill having for its object the qualification of a class of pharmaceutical chemists in Ireland."

This announcement we think worthy of earnest attention, because it appears to us to convey the final abrogation by the Apothecaries' Company of their legitimate function of controlling the practice of pharmacy in Ireland, and because it gives the signal for the introduction of counter practice into Ireland. It might have been hoped that the failure of the attempt to constitute themselves a qualifying corporation in medicine and surgery would have induced the Apothecaries' Company to revert to the duty of regulating the practice of pharmacy, which they have neglected so lamentably and with such ill results to the profession in Ireland; and it is much to be regretted that the Governors prefer to consign the Company for ever to the oblivion which now involves their medico-surgical licences, and to hand over to new claimants the function under which their ancestors enjoyed public respect.

The comparison of the Irish Apothecaries' Company with its sister corporation in England might be sufficient to teach its Governors wisdom. In England the licence of the Apothecaries' Hall is well known and widely esteemed as a guarantee for proficiency in every department of pharmacy, insomuch that the licences of "the College and Hall" are almost an essential title to general practice. The London Apothecaries' Company stick to its last with such persistence and industry that all the world appreciates the value of its licence as a guarantee of pharmaceutical proficiency which can be had nowhere else. The Dublin Apothecaries' Company, on the other hand, offers for public acceptance a nondescript certificate that the holder is "Jack of all trades and master of none," and by its vain pretension to qualify in subjects foreign to its capacity or its functions, it discredits the legitimate guarantee which it did once give and might still confer of pharmaceutical proficiency. The L.A.H. London is, in fact, a reliable certificate in a special department of medicine, and as such everyone looks for it. The L.A.H. Dublin is a vague and pretentious diploma of proficiency in the whole art and mystery of medicine, surgery, pharmacy, and all its collateral sciences, and as such it is hardly heard of even in the Dublin schools as a possible object of the student's aspiration. Only a few weeks since we noticed the statement of Mr. Langley, the most influential medical agent in England, to the effect that Irish students made very good assistants *as soon as they had acquired a little knowledge of the apothecary's art.* To-day we find the Irish Apothecaries' Company, in the face of this statement, and in the absence of the slightest public guarantee for the purity of pharmaceutical practice in Ireland, still strong in the determination to maintain their pet theory that they are in any real sense a licensing corporation in medicine and surgery, and handing over the public safety in their own special department to other hands. After all we have nothing to regret, for we look forward to the time when the Apothecaries' Company shall have receded into indefinitely distant oblivion, and their place shall have been taken by the class of highly educated and industrious chemists of which the Pharmaceutical Society of England has reason to be proud.

◆

SCOTLAND.

EDINBURGH.

ROYAL INFIRMARY SITE.

Diversity of opinion still prevails on this subject. It is considered that the subscribers to the New Medical Hospital are a distinct body from the contributors to the Infirmary, which increases the difficulty as to the ultimate decision. The committee of the contributors have issued their report, which shows that the majority were of opinion that the best situation will be on the grounds of St. John's Hill, to the east of the existing Surgical Hospital, as delineated in Schemes Nos. 2 and 3 of Mr. Bryce's Report to the Managers, of date January 14, 1869. By either of these two schemes, they think, an admirable and very healthy site will be obtained, with great air-space which cannot be interfered with, and great facilities for drainage. The report also stated that they had carefully considered the site of George Watson's Hospital, and were of opinion that this site is inferior, in open air-space and general healthiness, to the sites of Schemes Nos. 2 and 3; that it is lower than the ground on the east, west, and north sides of it; and that, in particular, there is much difficulty with regard to drainage. It appears, too, that the latter will involve the largest outlay. Still it is a question whether, for several reasons, the grounds of George Watson's Hospital may not be the best site after all; and if the details of Professor Syme's letter to the Managers, dated October, 1868, and the paper read by Dr. Andrew Wood at the Medico-Chirurgical Society, to which we referred in our issue of December 23, are at all worthy of notice, there can, we think, be little doubt that such is the case.

THE WATER SUPPLY.

Mr. Lewis, at the meeting of the Town Council, moved that the Council should approve the report of the Special Committee, and resolve to prosecute the Bill now in Parliament for taking over the Water Company's undertaking and carrying out the St. Mary's Loch Scheme. Two amendments were made, but Mr. Lewis's motion was carried by a majority of 24 to 5.

THE UNIVERSITY COURT.

At a meeting of this Court on the 16th inst., Dr. Wm. Robertson, F.R.C.P.Edin., and Mr. Benjamin Bell, F.R.C.S. Edin., were re-appointed Examiners in Medicine for one year; and Dr. J. Warburton Begbie, F.R.C.P.Edin., was appointed Examiner in Medicine for the same period, in succession to Dr. Wm. Seller, who had intimated that he did not desire re-election. It was resolved to submit to the General Council, for their consideration, a proposal to exact a fee of ten shillings from all persons, not being matriculated students, who should present themselves for examination at the preliminary examinations for graduation in medicine.

VETERINARY COLLEGE.

We understand, says the *Scotsman*, that Dr. G. W. Davidson has been appointed to conduct the duties of the Anatomy Chair—vacant by the death of Prof. Strangeways—until the close of the session.

ST. ANDREW'S.

The installation of Mr. Froude, Lord Rector of the University of St. Andrew's, is expected about the middle of March. Mr. Froude has nominated Mr. John Skelton, advocate, Edinburgh, to act as his assessor in the University Court.

GLASGOW.

SOCIETY FOR PROMOTING EMPLOYMENT OF WOMEN.

The chief object of this Society is to facilitate communication between employers and all kinds of female workers, in pursuance of which object opportunities present themselves of helping the deserving and industrious in a variety of ways. The amount of remuneration is left entirely to be settled between employers and employed. In the year there were 397 applications for employment, 458 applications from employers, and 396 situations procured.

ABERDEEN.

GORDON'S HOSPITAL.

After the routine business of this institution was finished, Dr. Fiddes was elected medical officer to the hospital in the room of the late Dr. Dyce. It is contemplated to select twenty boys, or such number as may be considered desirable, from those who have not been less than two years in the hospital, whose conduct and attainments are the most meritorious, who shall be sent to the Grammar School for education there in such branches as may be considered most suitable for them. The consideration of this was remitted to the Education Committee.

ABERDEEN UNIVERSITY.

At a recent meeting of the Senatus Academicus, Dr. Pirie was unanimously re-elected assessor in the University Court for the next four years. It is stated that Dr. Arnott has transmitted to the Senatus of the University £1,000 to be employed in founding one or more permanent scholarships in the experimental branches of Natural Philosophy. For the past three years this gentleman has given £50 each year as a prize to the most distinguished student in the magistrand class in this department. This generous donation has made the prize permanent.

NICE.—THE SEASON.

THE SANITARY CONDITION.

(FROM AN OCCASIONAL CORRESPONDENT.)

The present season has been as unfortunate for the Nicois, or, as they prefer to be called, the Nizzards, as it has for the visitors. The former, and the swarm of hotel-keepers, shop-keepers, and others by whom they are reinforced, lament that their lawful prey, as they consider the latter, have not arrived in sufficient numbers. The latter complain bitterly of the weather, and declare that the climate has undergone a complete change. And truly there seems at times reason for this. During November and December, which ought to consist of one continual time of sunshine and warmth, there were scarcely three successive days such as we are accustomed to call "true Nice weather." Clouds and rain, and then "clouds returning after the rain," made it impossible for us to realize that we were at Nice; and I, with seven years' experience, and a friendship with many natives, went about enquiring despondingly what had become of the Nice sun, that used to be so powerful, but could not disperse the clouds of 1868. I waited patiently for the new year, having observed that sometimes the season, when the rain continues so late, clears up at that time, and a milder January makes amends. I hoped that the Spring winds would be later, and thus we should enjoy December weather now. But I was to be disappointed. January set in with the same veil of clouds. The rain continued at intervals. Worst of all, the winds have set in with all their fury, and now dust, aptly called the scourge of Nice, frequently renders it impossible to go out, except at the risk of suffocation. As I write in my room immense pyramids of fine white dust are careering along the promenades, chasing each other with a fury that only the whirlwinds that shape them can simulate. Here and there two or three of them meet and blend into each other, or, instead of that, commence a battle that scatters the suffocating particles far and wide. Woe to the passenger who is present at the point of contact! Hat, bonnet, sunshade, cloak, everything is sacrificed. Black hair, beard, and moustaches are left grey after the onslaught. The apparel of ladies is still more cruelly treated, not unfrequently much of it inverted over the hapless head; while, in any case, the victim, male or female, is left half-blinded, hands covering eyes, smarting with the pain and weeping scalding tears, and mouth wide open—gasping for breath, panting for moisture. Verily, for persons with irritable or diseased air passages, whatever those of our profession who have not seen it may say, I can conceive of nothing worse, and this leads me to state that I have met with persons here, sent by celebrated London physicians, on whom the climate acted as a poison, and who suffered terribly from the wind and dust as well as some other inconveniences, whose end seemed to be rapidly accelerated by what was to save them. It is time that our brethren who know nothing of the place sent their patients to those of us who do before letting them run such risks. I could name three or four men of high reputation who will not again enjoy the confidence of numbers who have witnessed the sufferings of their patients here during the last two or three months. One poor gentleman was doing so very badly, so rapidly dying in fact, that some ten days ago he was carried into a train and undertook the long journey northward as the last chance. But the peril of doing this is great, especially in mid-winter. Numbers of others have left for Rome, Pau, Pisa, San Remo, and other places reputed to be milder. It is, in fact, now being recognized that most people should leave Nice as soon as possible after the beginning of January, in order to avoid its winds and dust. The season consequently grows yearly shorter. Sometimes the winds hold off till February; but unhappily, as I have said, this year they are early.

There is another inconvenience and danger at Nice, which, inasmuch as it can be removed, ought to be brought again to the notice of the authorities. I mean the foul smells arising from the neglect of drainage. This is a growing evil that threatens the prosperity of the town as nothing else does; for there are numberless people who will come to Nice for pleasure if it is not necessary for health, but who would vanish on the outbreak of a pestilence. The rapidity of its growth is almost incredible, the apathy about sanitary laws disgraceful. During the last three years Nice, so far as the visitors' quarters are concerned, has almost doubled. The river has been embanked and all along one shore new houses of enormous size have been erected. Those familiar with the place two or three years ago would scarcely know it now. Chauvain's Hotel used to terminate, so to speak, the quay named after Massena. At any rate, few English cared to venture farther along the broken ill-smelling route towards the Lyceum. Now the quay has been prolonged to the latter building, the ground having been raised to the level of the other part, and the "Grand Hôtel," in imitation of its namesake in Paris, and the "Grand Hôtel de la Paix," have sprung up, and form a noble portion of the new street. Besides all this, alterations have also been made, and even Chauvain's comfortable old house, not to be eclipsed, has had to put on a new face, so that its former guests would scarcely recognize it. Besides these, a host of new hotels and new houses, and a number of new streets, have been called into existence and need draining. I say emphatically that all this addition, while the drainage of the town is left *in statu quo*, constitutes a serious danger, and I will give you a few facts to prove how clearly this is showing itself. Nearly opposite the new buildings I have named some sewers open into the

Paglione. Now, this torrent or stream—often as it is dignified by the name of river—seldom contains much water. It is a very wide pebbly bed, which, once in a few years, at the rainy season, is covered by the rapid stream, but usually contains only one or two threads of water, with little pools at intervals, where the native women may be seen washing the linen of the visitors. They have been described as picturesque objects, and some poetically inclined writers have gratified their sentiments by painting them in words of admiration. I confess, however, that I cannot look at them and forget that the pools in which they pursue their industry are now little else than diluted sewage. Again, it is a practice that cannot be too severely condemned, to make the Paglione the réceptacle for all kinds of filth and rubbish. I have seen carts empty into it something in comparison with which the London scavenger's and dustman's load seemed sweet. Following its course down to the sea, the same offence becomes at every step still more perceptible. The "Public Garden" is bounded on one side by this river-bed, on another by the sea. A few years ago it was a delightful place, and now it retains its prestige as a fashionable lounge; but time after time this year, going to hear the band play, my nose has been assailed by indescribable stenches, and I am sure it is best to forego the lounge in the garden. Nor is this place exceptional. From it the *Promenade des Anglais*—the fashionable walk and drive—has been prolonged some two miles along the shore. Here it is that the wealth and beauty of the season most delight to go. Every few paces some fine hotel or boarding or lodging-house is located. Only Naples may compare with this promenade; but assuredly it is too much like Naples in its abominable smells. From most of the larger buildings a tube carries the sewage on to the beach, where it festers in the tropical sun—an ever-present danger. Surely, only the excessive rarity of the air saves the town from devastation. The Casino, the finest building of all, was opened last year. It is close to the public garden, looks on the promenade, and at this spot there is generally the greatest crowd; here, on a fine day, people walk or sit down and chat, protecting themselves from the sun by thick, light, cotton umbrellas, but exposed to all the evils that such noxious exhalations may induce. On the beach just below them there is a most offensive smell, which has often driven me away. Whether it proceeds from the drain of the Casino or of the adjoining hotel I will not pretend to decide. I testify the smell is there, but further this deponent sayeth not.

I might go on to describe many other equally offensive spots, which are growing worse day by day, and are rapidly tending towards the destruction of Nice as a health-resort. Let these examples suffice. Surely those whose duty and those whose interest it is will accept the remonstrance of a friendly observer, and take some steps to avert the danger. Yet I fear that is by no means certain, for last year many complaints were made, and numerous promises were thereupon given—none of which seem to have been fulfilled. The inhabitants do not like any allusion to such things, and in their fear of being injured they systematically deny the most obvious facts. Some of my friends took great pains to obtain some reforms, and quite expected this year to find their suggestions had been carried out. I am too well acquainted with the place and the people to have indulged in these anticipations; but now that the evil assumes such a magnitude it is high time to utter a warning. The fact is, nothing but the fear of a bad season has any influence. Last winter was as exceptionally fine and brilliant weather as this has been the reverse. Then, too, the visitors were as numerous as they are now few. Encouraged by that the inhabitants believed that all would return, bringing others in their train, and are now doubly disappointed. In their expectation of a second good season they neglected the advice tendered them on every hand, and forgot that many who enjoyed the continual sunshine protested against the increasing filth. After the long period of fine weather last year the offences I have described were more perceptible, and all the finest walks were pervaded by the pestilential exhalations. This season the unusual wet and cold has tended rather to abate the nuisance, and so give us some compensation for our disappointment in getting only occasional glimpses of the bright sun and blue sky we come so far to seek.

Notes on Current Topics.

The London College of Physicians.

The reforms contemplated have been postponed. The efforts made result in a *fiasco*. By a sheer accident the hopes of those who built on Dr. C. J. B. Williams have been shattered. The Conservatives of Pall Mall have won by a fluke, as sporting men would say; but their triumph will be brief. They may moderate their rejoicings, for the spirit of freedom and the love of justice have been roused, and it will be impossible for the venerable College to continue for many years the hole-and-corner proceedings that have led to so many abuses. Much has been done, say some. Yes! It may be so. The deserted room has been entered. The dust of generations has been stirred. The rats have been disturbed. It must not end here, or the dust will settle down again, and the rats will continue in sole possession. Now we have begun we must cleanse and sweep the place, and dedicate it to better uses.

The London College of Surgeons.

Economy is the order of the day, and so thoroughly has the idea penetrated every class, that some have been rash enough to hint that our Royal Colleges might be none the worse for a period of retrenchment. The London College of Surgeons is the guardian of the most magnificent Museum in the world, and few would like to see a curtailment of that monument to Hunter. But the Museum costs the College a couple of thousand pounds a year, and that is a serious item. The nation has given in different grants nearly sixty thousand pounds for the Museum, building, &c. But the College has been more liberal, has, in fact, expended not only an equal sum, but nearly one-third more. Yet who would willingly see the Hunterian Museum languish? Ought not other economies to be first practised, for assuredly some retrenchment will be needed to save the College. The medical reforms looming in the future will diminish its income unless its own reform shall be the most popular—a consummation few dare to hope for. How about the Examiners? Perhaps a more economical system of testing candidates could be managed, and at the same time one that would lead to essential reforms. It will long be doubtful to most men whether ten Examinerships should be the goal of surgical ambition, and the pecuniary recompense of collegiate age. Looking over the accounts, such as they are, we fancy we see other items that require explanation. The members of the College are interested in these things. Is it not their cash paid for the diploma which is the only resource of the College? Should they abandon all interest in their College when they have paid their twenty guineas, and received the right to call themselves M.R.C.S. Eng.?

Death from Chloroform.

On Sunday, Feb. 14th, a chemist of Sheffield, named Godley, died under the administration of chloroform. He was about to undergo an operation for the removal of a piece of diseased bone from the leg; and, although he seems to have felt exceedingly nervous about chloroform, it was, nevertheless, at his own request that this anæsthetic was administered.

The patient's heart and lungs were examined prior to the use of the chloroform, and the quantity employed was exceptionally small; yet, after inhaling for but three minutes, the heart ceased to beat, and the man was a corpse.

It is impossible to say, in this instance, how far the great fear and apprehension of the patient may have contributed to the fatal event, for we have heard of those who have died suddenly on the operating table, from the mere dread of the surgeon's knife, before the days of anæsthetics. It has always seemed good to us, in cases where any extra precaution is advisable, to use chloroform mixed with ether, or else to employ the bichloride of methylene. The nitrous oxide gas, perfect as an anæsthetic in dental surgery, is hardly as yet adapted to produce lasting anæsthesia for prolonged surgical operations.

The Hunterian Oration.

THIS biennial discourse was delivered at the College of Surgeons on Monday, the 15th inst. by the President, Mr. Quain. After a short review of the life and doings of John Hunter, the orator made some remarks on the subject of the shortcomings of general education in the present day.

Mr. Quain lamented the imperfect acquaintance with their mother tongue possessed by many in the so-called educated classes, and wished to urge upon the instructors of youth that more time should be devoted to English composition and less to the Greek and Roman classics. When, in the course of the address, we listened to the apt, tasteful, and distinctly uttered Latin quotations of the distinguished orator, we admired his well-stored mind, and were distressed to hear afterwards his ideas on classical education. Years ago, when Latin and Greek were made much more of in schools and colleges than they are at present, English composition, if we may judge from the writings of the time, was certainly not to be complained of; and we believe that infirmities of diction, composition, and even spelling, in the present day are among the early fruits of the commencing depreciation of the study of Latin and Greek.

Winter at Home and Abroad.

THAT the weather has been "all wrong" this year has become a common saying in England, and judging by our correspondence—a pretty wide one, by the way—the same remark is applicable on the Continent. While the whole of the British Isles have enjoyed an exceptionally mild winter, some of the most highly favoured health-resorts in the South of Europe have had an unusually severe one. From Yorkshire and parts of Scotland we hear that March and April flowers were blossoming in the beginning of February. Residents in Eastbourne boast of their geraniums having been in excellent condition about the same time. Only four or five nights of frost have been noticed in many localities. In our own most southern resorts we are told of gardens in a forward state scarcely credible, and in our northern and eastern counties even broccoli run to seed, and pears and apricots begin to blossom. Our Special Correspondence from abroad tells us of biting frost in Naples, Rome, and other parts of Italy and France that do not often thus suffer. Dr. Hawkins and other correspondents have described Nice, &c., in our columns. These contrarieties are of great importance, and will be noted by meteorologists as well as by those who have made a special study of climates and their influence in health and disease.

Of course we are not pretending that the English climate equals those of more southern sheltered districts as a home for all invalids or a locality to pass a pleasant winter, but we wish to draw particular attention to the great variations to which such places are liable, and the care that should be exercised in their selection. We commend to the reader's serious attention the letters and communications in course of publication in this Journal.

Charity.

THE synopsis of reports of London charities that appeared in the *Times* of the 11th will be of great value to those who are studying the subject. Of course it cannot be complete, but it is an excellent basis for further work; and we trust our readers will gladly respond to the appeal that has been made for further information. Not a few must know all the particulars of hospitals and other charities, and we can conceive of no better employment of that knowledge than placing it at the service of the gentleman who has done so much and is ready to do more Mr. Hicks has systematically commenced a work which may be continued, becoming at each revision more complete and more exact. The *Times* has done well in giving him such an extraordinary share of its space, and we hope all will be ready to contribute such items as they can.

The late Joseph Hodgson, F.R.S.

THIS gentleman, who had filled all the high posts at the Royal College of Surgeons, has passed away at the age of 82, under circumstances to excite unusual emotion. It was thought he might some time survive, but the sudden and unexpected death of his wife caused such a shock to the aged surgeon that he himself died the next day (the 7th inst.). His diploma of M.R.C.S. bears the date November 15, 1811; and he won the Jacksonian Prize that year, the subject being "Wounds and Diseases of Arteries and Veins." He was, in the early part of his career, Surgeon to the General Hospital, Birmingham, but at length removed to the metropolis, and acquired a large practice. He obtained a seat at the Council of the College in 1849, delivered the Hunterian Oration in 1855, was made Examiner in 1856, and in 1864 passed to the President's Chair. He contributed many choice specimens to the Museum.

The Carmichael Essays.

THE Master of the Rolls for Ireland last week delivered judgment as to certain alterations proposed by the Council of the Royal College of Surgeons in Ireland in the scheme for the granting of these prizes, as set forth by the founder, Mr. Carmichael. The expressed intention of Mr. Carmichael was, that the interest of the £3,000 bequeathed by him should be expended every four years in the grant of two prizes, of the value of £200 and £100, for the best essays on the subject of "Medical Education." These prizes were to be awarded by the verdict of three jurors chosen by lot from the Council of the Royal College of Surgeons in Ireland, and if these judges declared the merit of the competing essays insufficient, the Council had power to postpone the award for a further period of four years, and, if they saw fit, to double the prizes at the end of that time. This contingency did, in fact, arise, for the essays forwarded four years ago for competition were declared unworthy, and no award was made till last year.

As many of our readers are aware, the prizes were then adjudged to Dr. Mapother, Professor of Anatomy and Physiology in the College, and to Dr. Isaac Ashe, of Warrenpoint, Local Secretary of the Medico-Political Association; but the Council declined to double the prizes, as the provisions of Mr. Carmichael's will entitled them to do. It was then ascertained that the four years' interest would be insufficient to meet the cost of the adjudication and publication of the essays and the amount of the prizes. The prizes amounted to £300, the publication and advertising of the two essays to about £100, and the three judges voted £50 each for their labour in reading the essays and reporting on them; and it thus appeared that not only was no provision made by Mr. Carmichael for this latter charge, but that the sum set down for publication and contingent expenses was totally inadequate. When we state that, at the competition four years since, thirteen essays were sent in, and that one of them consisted of five volumes of microscopic writing, and filled a large box, it is obvious that no Member of Council could be asked to undertake the perusal of them with the requisite care without remuneration for the duty. In point of fact, such a duty would constitute a penalty on Councillorship which few persons would willingly incur.

To meet the difficulty of deficient funds the Council proposed to depart from Mr. Carmichael's intention to the extent of awarding the prizes every six years, instead of every four, and they submitted a scheme to that effect to the Master of the Rolls. Inasmuch as it was provided by the testator that the money, in case of there being no award, should pass to the Royal Medical Benevolent Fund Society of Ireland, the Council of that Society were interested in the arrangements, and, after due consideration, they assented to this proposal of the Council of the College, and approved of the award to adjudicators. The Master of the Rolls has, however, now decided that, as Mr. Carmichael omitted to make provision for this outlay, it cannot be now provided for, and the adjudication must be effected without remuneration, if at all. Under these circumstances we anticipate that at the next period of award it will be found impossible further to carry out the intentions of the testator, and the fund will probably pass to the Royal Medical Benevolent Fund. We imagine that the profession will regard with satisfaction this solution of the difficulty as one more advantageous than the publication of wordy compilations or impossible propositions in medical education.

The Recent Contest for the Representation of the City of Dublin.

The Committee for promoting the return of Sir Dominic Corrigan have issued within the last week in book form a record of their recent proceedings in furtherance of that object. The prefatory matter, as might be anticipated, strongly advocates the superiority of professional over political considerations, and with consistent vehemence denounces the conduct of those members of the profession in Dublin who thought it their duty openly to oppose the return of Sir Dominic Corrigan.

The transactions of the meeting of the profession, held in the Molesworth Hall, in support of Sir Dominic Corrigan, are reprinted *in extenso*, and a list of the subscribers to the election fund complete the volume. The publication is admittedly *ex parte*, and will be therefore read with the necessary reservations.

Criminal Abortion in America.

The foulest social stain which it is possible can attach to a community—that of habitual fœticide—has been pointed out with indisputable distinctness and authority in the work on Criminal Abortion recently published by Dr. Storer, a Fellow of the American Academy of Arts and Sciences, and, jointly with him, by Mr. Heard. It is not, we believe, too far for us to go if we aver that the procurement of abortion—premature child murder—is a practice so frequent amongst the women of the upper classes in the United States, and so well recognized an "institution," that it is hardly thought necessary to conceal it. Within our personal knowledge an American "lady" boasted to her English friend that she need never be troubled again with the pains and penalties of her sex, for that when she found herself in the family way she "took pills" and set matters right.

Dr. Storer furnishes the following statistics:—In the city of New York, in eight years from 1848 to 1855, the number of premature still-births amounted to 2,078, and 10,792 still at the full time; showing an average of 1 in 5. In 1856, the average was 1 in 4·02.

Dr. Harris estimates that an eighth of the still-births in New York are now (1868) at the seventh month. That abortion is steadily increasing is proved by statistics in this country, and confirmed by foreign records, which, by the way, are abundantly quoted.

Happily, the Women of the Period are not yet Amberleyized up to the American point, and with them child-murder has not acquired the dignity of refined Malthusianism or advanced Liberalism.

Hospitals for the Sick Poor.

A letter from the Poor-law Board was read at a meeting of the Metropolitan Asylum Districts Board on the 13th instant, the substance of which was that they had reconsidered the question as to the number of hospitals which it may be absolutely necessary to erect, and they suggested whether it would not be more expedient to build two of them only, and reserve their final decision as to the third. Time, they thought, should be afforded to ascertain by actual experience whether there would be sufficient accommodation in the two hospitals at Homerton and Stockwell, and if further permanent accommodation was found necessary, then the third at Hampstead might be built. Meantime, for any sudden outbreak of fever temporary buildings might be erected on that site. The Board are desirous of ascertaining the views of the managers after they had reconsidered the subject. The question will therefore again be brought forward at some other time.

Indian Medical Service.

The following is the list of the Candidates for Her Majesty's Indian Medical Service who were successful at the competitive examination at Chelsea, on the 8th of February last.

Thirty-eight candidates competed for twenty appointments. Thirty-six were reported qualified.

The profession in Dublin is at this moment interested in the retirement of one of its members from its ranks under peculiar circumstances. A physician practising principally in the treatment of skin diseases, and holding office in the King's and Queen's College of Physicians, has, we understand, decided on relinquishing the practice of the profession altogether and going into the Church. The gentleman in question is well-known to many of our contributors as having acted for some time as sub-Editor of the Irish Department of the Medical Press and Circular, and as having subsequently become connected with another medical periodical under circumstances on which, at the time, we thought ourselves called upon to animadvert. Shortly afterwards he became a candidate for the Registrarship of the College, in the competition for which he was defeated by the late Dr. Guinness. His name was next publicly mentioned as the probable successor of Dr. G. H. Kidd in the Editorship of the *Dublin Quarterly Journal of Medical Science*, but the arrangements were not completed, and the management of that journal devolved upon Dr. Little, under whose able and acceptable supervision the first number has just appeared. Within a few weeks, the lamented death of Dr. Guinness again created a vacancy in the Registrarship, for which, however, the physician to whom we allude did not think fit to compete ; and we now learn that by his decisive and ultimate retirement from the profession his connection with our medical contemporary has passed into other hands.

The gentleman's intimate connection with an ultra Ritualistic Church periodical in Ireland prepared the profession to a certain extent for the step which he has now taken.

Even with most earnest desire to forget the means and circumstances under which our former sub-Editor connected himself with an avowed competitor for the journalistic patronage hitherto accorded by the profession in Ireland to the Medical Press and Circular, we cannot refrain from giving utterance to some allowable self-jubilation on the utter collapse of a scheme for undermining our influence, built upon connection with our journal.

This evening, at half-past seven o'clock, the first meeting of the London Students' Debating Society will be held at the Botanical Theatre, University College. Dr. Sibson will deliver an opening address.

The President of the Poor-law Board visited the Marylebone Workhouse lately. He found that the Guardians had carried out the orders and rules of the Board, and much improved the buildings. But there are other workhouses which require strict visitation, as there is in them great neglect of the sick poor.

The *Gazette des Hôpitaux* announces that subnitrate of bismuth has been employed in large doses with wonderful success in Algeria as a specific for dysentery.

It was stated by Sir S. Waterlow, M.P., at a meeting of the Industrial Dwellings Company, that the buildings are progressing, and that they are let as fast as they are completed. The object is to provide healthy dwellings for the working class in a way that will not interfere with their independence and self-reliance.

On the 16th instant, the Isle of Wight Union Workhouse was visited by the Queen. Her Majesty was conducted over the establishment by the governor and matron.

Several cellars have been closed at Liverpool by order of the stipendiary magistrate. This was done at the instance of the Health Committee, who considered them unfit for human habitation. Some of the persons occupying them were summoned and fined. One woman, upwards of seventy, said she had lived there more than twenty years, and could not conceive why she should be molested.

The Malvern Lying-in and Samaritan Charity held their eighth annual meeting on the 16th instant. The report stated that 150 poor women had been attended to in their confinement during the year without loss of life. Since the institution of the charity 975 cases had been attended professionally with only one casualty. A gratuity of ten guineas was offered to each of the medical practitioners.

We learn that to-morrow (the 25th) an ordinary meeting of the Metropolitan Counties Branch of the British Medical Association will be held at 32A George street, Hanover square, at eight p.m., when Mr. E. Hart will open a discussion on hospital administration, and will bring several important topics before the notice of the meeting.

---

* Obtained the Herbert Prize.

The report which was read at the annual meeting of the Governors of St. Luke's Lunatic Asylum, after giving statistics of accounts and of patients, stated that the Lunacy Commissioners had visited the hospital, and quoted the following extract from their report :—" With few exceptions, we found the patients in a favourable state. Not one was suffering from any degree of excitement in either side of the hospital, and their appearance both as regards dress and tidiness and generally as to bodily health and condition was throughout very satisfactory."

Correspondence.

UNIVERSITY COLLEGE HOSPITAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your paper of January 27th, I observe some remarks calculated to reflect injuriously on an Institution at which I had the privilege of being a student, and to the medical and surgical staff of which I feel I owe a daily increasing debt of gratitude.

It is said, at page 77, that the medical officers of University College Hospital " surrender their fees to prop up a small institution which is always in debt, and only gets a fair supply of surgical cases when a house tumbles down, or an unlooked-for railway accident occurs in the immediate neighbourhood." Now, as to the " Debt " part of the question, I do not see that here University College Hospital is any worse off than a host of other unendowed hospitals which have annually to get from the public something in addition to the regular annual subscriptions in order to make up for the excess of expenditure over regular income.

With respect to the supply of cases to the hospital, I know that when I was a student there surgical injuries of all kinds were constantly coming in, not only from the immediate vicinity of the Hospital and from the immense railway termini which are so close at hand at Euston and King's Cross, and to which we may now add the new St. Pancras Terminus of the Midland Railway, but I have seen cases of recent injury brought from some distance on purpose to receive treatment at the Hospital. With surgical diseases of interesting and instructive character the wards were well supplied, and anyone who might be at the hospital at two o'clock on Wednesday might be almost sure to see one or more good operations, and hear the previous history of the case told briefly but concisely to the assembled students.

For clinical teaching, both surgical and medical, in the wards, and in the out-patients' rooms, University College Hospital has always been celebrated ; and I have heard students from other hospitals of London of highest repute remark on the excellent clinical teaching of the Hospital when they have been going round as visitors to the wards.

I am, Sir, yours obediently,
John C. Thorowgood, M.D. Lond.
Welbeck street, W., February 9, 1869.

PAUPERISM, CHARITY, AND THE POOR LAWS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am very glad to see you have devoted some of your valuable space to the consideration of Pauperism in its various forms, and that you have not excluded articles with which you do not altogether agree. It is of importance to the nation that such a subject should be fully ventilated. Of all classes none is more interested in it than our own profession, and I therefore hope you will continue with the impartiality you have evinced to lay before us the thoughts of the " good men and true " amongst us who take the pains to put them in shape for our benefit, and all of whom are as worthy of being heard as the hasty writers who turn out so many crude articles weekly for your contemporaries.

Yours, &c.,
Impartial.

DUBLIN SCHOOLS AND DUBLIN DEMONSTRATORS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Allow me space for some remarks on the line of tactics pursued by the heads of Dublin schools with regard to demonstrators of anatomy. I am induced to trouble you with these remarks, because I am personally affected by their policy in this respect, and because I believe, if it be persisted in, it will impair the efficiency and lower the status of Dublin as a school of medicine. The line of tactics to which I take exception is the habit of appointing a number of demonstrators in the different schools out of all proportion to the requirements of teaching. This habit, as I shall show, inflicts grave injury on the real working demonstrators, and is followed by results the reverse of advantageous to the students.

In London, where the closeness of the union between the school and hospital imposes a double duty on the staff, we find seven schools with not more than two demonstrators, three with three, and one only (Guy's) with four. Here, with a smaller average of pupils and lighter work, most of the schools have twice this number, and some of them nearly three times as many as Guy's Hospital. Why this large number in Dublin ? It is not that our neighbours have less than they require to work their schools efficiently ; for if we look to results we find that the students they turn out are at least as good practical anatomists as ours. This would not be the case if they were under-demonstrated ; nor am I aware of any special obtuseness in Irish intellect that necessitates it. The ridiculous number of demonstrators here is due, not to the fact that they are wanted, but to the fact that the heads of schools think that their success depends on the length of the string of names which they bring before the public.

But what harm does this yearly relay of newly-fledged birds do to any one ? Very great indeed to the working men of the school. The prestige of the office is seriously depreciated by it.

Now, *bonâ fide* demonstrators, by which I understand those who take more or less permanently to this department, have been, and are, paid more by the status which they derive from the office itself than by any emolument which they draw from it. Hence, if you strip the office of all dignity, which you do by unlimited and unnecessary appointments, you inflict on them a great injustice, and from the services rendered by them it becomes oftentimes a case of robbing the tiller of the fruit of that which he has sown. The entire school staff is also injured. A connection with a school is supposed to favour practice ; but of what advantage can it be towards that end if the public find that the name on every second house through town is that of a gentleman connected with teaching ? Owing to this superabundance of " lecturers," school connection has lost, and is losing every day in the eyes of the public, more and more of the value formerly attached to it. The wonder is, that they should still attach any value at all to a position which can be got for the asking.

No man becomes a surgeon by always looking at others operating. No student becomes a practical anatomist by always listening to demonstrations. The one must operate, and the other must dissect, if either is to become the anatomist or the surgeon. The student is simply ruined by having everything done for him. Now this is what obtains under a system of over-demonstrating. Need we be astonished, therefore, if we find that two out of every three of our Dublin students could, if called on, dissect with about the same amount of neatness the coverings of a hernia or the structures that overlie an artery the day they bid adieu to the dissecting-room, as they could the first day they entered it ? For aught of practical knowledge they possess two years after passing, they might as well never have shown themselves in a dissecting-room.

In Dublin, students are spoon-fed and made idlers of ; in London they obtain just that amount of assistance needed to enable them to work for themselves. Need we be surprised if the results be different ? Is there any gain to anybody to set off against the injury done to working demonstrators and student ? Parents and first years' students are, as it seems to me, led to make choice of this school or that by other considerations altogether. The non-professional knows nothing about such personages as demonstrators. A school prospectus is to him three-fourths unintelligible. The senior student does know ; and, aware of the number really required to work a school properly, merely smiles, if he bestow a thought at all on the matter. If the parties will only look into the history of the different schools, they will find abundant reason for coming to the conclusion that there has been, and is, no connection whatever between the prosperity of a school and an unnecessary number of demonstrators. If they continue, as at present, they will in a few years so debase the position that no person of merit will be got to accept it. When the age of part payment by position will have passed away, the only inducement which will provide them with men of the poorest abilities will be large salaries. This the resources of the schools will not admit of. The charge of students must then be given to men incapable of teaching them.

Now, Sir, as one of the *bonâ fide* demonstrators, I would ask the heads of the different schools to come to an honourable understanding among themselves to abate this nuisance and put some limit within the bounds of the actual requirements of teaching to the number of their junior staff. If they fail to do so, the duty of using a little gentle pressure will devolve on those who feel aggrieved by things as they are.

I am, Sir, yours, &c.,
T. Laffom, M.R.C.S.E., L.K.Q.C.P.,
Demonstrator of Anatomy Catholic University.

◆

PAUPERISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am glad you have decided as you say in the Notes on Current Topics, to give us the benefit of diverse views on this all important subject.

This accounts satisfactorily for the apparent inconsistencies between some of the articles that have appeared in the Medical Press. It is evident that three or four writers would not harmonize their views on a question on which no two people seem quite in unison. I confess to having read the article in your issue of the 10th inst., with much pleasure, although I am not prepared to accept its conclusions, nor as I understand, do you absolutely commit yourself to them.

I think one or two articles that preceded that, and especially those that referred to emigration, may be nearer the solution, but I am not so full of "false shame" as to refuse to consider the points set forth by your writer, who has evidently thought over the subject, and is thoroughly in earnest.

His views after all are infinitely preferable to the astounding notions that have been borrowed from continental socialists, and urged, I regret to say, by members of our profession; by some, too, who should know something of history, politics, and political economy.

Proceed, Sir, in the way you have marked out for yourself. Do not deny to able and thoughtful men the opportunity of addressing us in your columns; and a free expression of various opinions may add much to our knowledge, and promote the welfare of the community. Our profession is deeply interested in such subjects.

I am, &c.,
Medicus.

[We have already stated that our columns are open to different views on this subject.—Ed. Med. Press, &c.]

RELATIVE CHARACTER OF THE LONDON AND DUBLIN SCHOOLS IN SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I have lately had a warm discussion with my son, a newly fledged Licentiate of Dublin, on the relative superiority of the two Schools, he maintaining, with all his powers of argument and sophistry, that the Dublin School is preeminently superior and ranks higher than that of London. To this I demurred, and after several hits and counter-hits right and left, I left him *hors de combat*. The strongest argument used by me was the superiority of teaching, better hospitals, &c. I yielded to Dublin in anatomy and surgery, chemistry and materia medica, but the hardest hit was the system of cramming insisted on by the Dublin Court.

I compare the cramming system of teaching to the poulterer's coop—over-fed and wholly depending on their grinder, ever dissecting and seldom leading, while the London School is more appropriately compared to the poultry having a run of a good farm-yard, barn-door at hand, and the open gleanings of the stubble, all which conduce to the health of the bird and its fine plumage. You cannot attempt to go in to the Dublin College without having all the tips of the Court, the smallest and most insignificant, often totally devoid of practical value.

Thirty-six years ago I, intending to go to India, having received my education in Dublin between the Colleges of Physicians and Surgeons, was advised to take a London diploma. There I went, without any of the grinding or cramming, fresh from my anatomy room and Meath Hospital, under first-class men, never since equalled, viz., Crampton, Greaves, Stokes, McNamara, Collis, &c. I met the Court in Lincoln's-inn-fields, Guthrie, the celebrated army surgeon, being chairman and my first examiner. And on what subject was I taken? The amputation at the hip-joint, an operation never before heard of, much less seen by me. I was startled. My answering turned wholly on my knowledge of anatomy. The first step in the operation was the first question, and this I unflinchingly replied would be to take up the artery as it passes under Poupart's ligament. He brought me back several times to this, and I wound up by saying I would be firm in that first step because it would be hazardous to trust to compression by an assistant on the battle-field, where I calculated such an operation only could be required, but that I had most respectable authority against me.

At this I observed the nod of one of the eldest of the Court, a fine, handsome, portly man, who followed me to the door, saying under his breath, "You'll do."

I wrote to Dublin describing the examination, but would not be credited when I described it in the old hackneyed words *Veni, vidi, vici*. I am, &c.,
James John Johnston, M.R.C.S.Eng.

◆

Literature.

DISEASES OF THE LIVER.*

Since Dr. Budd's standard work on the Liver we have had nothing from an English pen with which we may compare Dr. Murchison's new volume; for the great work of Frerich's, translated for the New Sydenham Society, belongs to foreign literature, and, like some other books, is also of an essentially different nature. We make no doubt whatever that a clinical treatise by such a teacher as Murchison will exercise considerable influence over students and practitioners, and we are therefore gratified to be able to state the one before us is well worthy to do so. Gentlemen in full practice will do well to revise their notions of the part the liver plays in disease or indisposition by the light of this volume. It will enable them in many cases to substitute well-grounded reasoning for mere guess work; will dismiss for ever some notions that have long lingered obscurely in their minds, and enable them to think to some purpose on the problems that are now occupying some of the foremost minds of the profession.

Take, for instance, the question of the action of mercury on which Dr. Hughes Bennett has been engaged in experiments for the British Medical Association, and whose conclusions thereanent so surprised the great body of practitioners. Dr. Murchison has evidently carefully weighed the evidence, and he has come to a conclusion which is likely at present to receive the assent of the majority. He thinks that "mercury and allied purgatives probably produce bilious stools by irritating the upper part of the bowel, and sweeping on the bile before there is time for its absorption." He recognizes the fact that articles of food frequently give rise to similar effects, and thinks that their action is precisely similar. From this we might suppose that other purgatives should be substituted more frequently than they are, and assuredly this view supports the American preference for podophyllin, or, as it is called sometimes in the States, "vegetable calomel." We could certainly say much in its favour. Dr. Murchison considers calomel of great use in congestion of the liver, but if it increased the secretion of bile, it would have an injurious effect. He thinks it likely that "irritation of the duodenum by purgatives, may be reflected to the gall-bladder, and cause it to contract, and that the evacuation of the viscus may account in part for this increased quantity of bile in the stools." Dr. Murchison's is a handy sized volume. The former half treats of enlargements of the liver, under the division of painful and painless enlargements. The latter includes gall-stones, jaundice, hepatic pain, contractions, and abdominal dropsy. The cases upon which the lectures are founded are well selected and carefully related. Their study is likely to lead to more careful diagnosis and treatment.

MEDICINE.

BROMIDE OF POTASSIUM AND ANTIMONY IN PUERPERAL CONVULSIONS.

Dr. T. N. Simmonds reports to the *Philadelphia Medical and Surgical Reporter* the history of a case of puerperal convulsions, in which the efficacy of these remedies was evident. A primipara, while in labour, with the head of the child in the inferior strait, was seized with a violent convulsion, which was followed by four others, with an interval of about 15 minutes between each. Chloroform proving of no benefit, bromide of potassium was administered, beginning with a dose of 40 grains in combination with half a grain of antimony. In combination with the bromide one half grain of the antimony was given every hour and a half or two hours, until three grains of the antimony were taken. After the first dose there was a return of four paroxysms. The first occurred within an hour, the second in two hours, the third between three and four hours, and the fourth in eight hours. Their intensity and duration were also diminished in the order of their recurrence. Convalescence was rapid.

NITRATE OF SILVER IN THE TREATMENT OF UTERINE POLYPI.

Dr. M. M. Eaton (*Chicago Med. Examiner*) gives his experience in the use of the nitrate of silver in a case of uterine polypi which he treated successfully. The patient was 46 years old, of a nervous temperature, anæmic and emaciated. A digital examination revealed two small polypi attached by a long pedicle to the margin of the os uteri. These were soon discharged spontaneously, and she was free from hæmorrhage, for some months. An examination about a year after, revealed the uterus enlarged, and a considerable flow of blood mixed with pus. A sound producing an alarming hæmorrhage, a sponge tent was introduced and the os freely dilated. The finger being easily passed in the neck of the uterus, the whole surface was found thickly studded with polypi, from the size of a *grain* of wheat to a hickory-nut. To these the solid stick of nitrate of silver was applied, and the sponge tent reintroduced, to act as a tampon. On removing the tent next day, several small polypi came away, and the nitrate of silver was again freely used and the os left open. On the fourth day of the use of the caustic all hæmorrhage had ceased, and the tumours in the neck were all found to be detached and discharged. The uterus was then syringed with tepid water, and caustic applied to the suppurating spots where the pedicles had been removed, at the same time giving tonics and good food. This treatment was continued ten days, when she began to flow again very freely, and an examination revealed two large tumours in the cavity of the womb about the size of an orange. Ergot was given to cause contraction of the womb and descent of the tumours, and nitrate of silver was applied locally. By this means the hæmorrhage was controlled, but the caustic was applied for about ten days, when by forceps they were removed and the uterus left empty, though enlarged. By tonics and generous diet the patient entirely recovered, and has had no return of the polypi.

PHARMACY.

VARIABLE STRENGTH OF AQUA LAUROCERASI.

The introduction into the British pharmacopœias of 1864 and 1867 of aq. laurocerasi has had a marked effect upon the consumption of this preparation, the demand being now at least two or three times greater than it was five or six years since. Those engaged, or who have had any experience, in the distillation of essential oil of almonds well know that the longer the almond, when thoroughly disintegrated, is in contact with water, the less is the product in the distillate of essential oil, as water is very favourable to the oxidation of the oil into benzoic acid. Many experiments which I have made at intervals during the last eighteen months show that immediate distillation of thoroughly bruised leaves, as soon as in contact with water, gave always a distillate superior in fragrance and equal in hydrocyanic acid, and, in some cases, slightly in excess of the latter, to those made after twenty-four hours' maceration. The main point, however, to which I would direct you is one of more importance,—the percentage of hydrocyanic acid obtained from leaves distilled at different periods, and the variable state of the cherry-laurel waters as found in pharmacy at the present time. The three periods at which I have made the water have been March, July, and November; the highest strength of prussic acid being obtained in March, when it reached 1·26 grs. of real acid in 1000 grs.; the lowest in November, when it was only half the strength, ·64 grs. of real acid in 1000 grs.; the distillate of July being nearly a medium between these—1·08 grs., real acid, in 1000 grs. The various distillates were examined from time to time; it was found that they had depreciated as much as 10, and in some cases 20 per cent. of the original quantity of acid. This depreciation in value of acid by age, and variable strength of the water, as obtained from leaves at different periods of the year, lead me to suppose, that if I examined the cherry-laurel water in the pharmacies in town, I should find such a difference as should not exist with such a powerful remedy, which is about one-twentieth of the strength of the dilute hydrocyanic acid of the Pharmacopœia. I found aq. laurocerasi varying as 53 does from 100, or some only about half the strength of others; in one case I found, upon obtaining a second specimen from the same source (within seven days) that water dispensed one week was but little more than half the strength of that of the previous week. Such discrepancies as these ought not to be found, and must not exist, if we wish to have uniformity in medicine, and the life of the public safe in our hands. *Pharmaceutical Journal.*

SURGERY.

FRACTURES OF THE LARYNX.

From a paper of some length on a case of triple fracture of the cricoid cartilage we extract the following observations:— L., æt. 30, in a quarrel was seized by the throat by a strong antagonist, who knocked him down, and held him for some seconds. He was unable to rise, or to articulate, and his face was deeply flushed; he was at once carried home to bed. Next morning, when seen by Dr. Gagnon, L. was in a state of extreme dyspnœa, and quite livid. On the sides of the neck, corresponding with the lower border of the larynx, were slight marks of ecchymosis. The cellular tissue of the front of the neck was emphysematous. No crepitus, or any movement of fractured surfaces could be felt. Leeches were ordered, and after their application the swelling diminished, and breathing becames so much easier that tracheotomy was postponed; however, in the course of the night, during a change of posture the patient died suddenly. At the post-mortem examination the larynx was carefully removed, and on dissection a triple fracture of the cricoid was discovered, along with a partial dislocation of the left arytenoid cartilage. Considerable œdema of the glottis was present. The death seemed to have been caused by a sudden displacement of a fragment of the cricoid and the corresponding arytenoid; which, pressing on the already diminished glottis, caused asphyxia. Other cases of this very rare accident are detailed. One recorded by Dr. Cavasse, caused by a fall down stairs—fatal. Another caused by a carriage accident, saved by tracheotomy, by M. Maisonneuve. Another caused by a blow from a piece of coal—recovered. Another recorded by Marjolin, when the thyroid was split by a woman's hand in a quarrel. Two others by M. Martin-Damourette and Plonck, in which instant death was caused by the fracture of the thyroid. Another set collected by Gibb, are well known in this country. Dr. Fredet divides the cases he has collected, for practical purposes, into two sets. 1. Simple fractures, which are accidents so trivial that rest and silence are sufficient for a cure. 2. Complicated fractures. A. causing instant death. B. accompanied by suffocation, cyanosis, &c. In these, death may occur at any moment from displacement of fragments or œdema; and tracheotomy ought to be performed as a precautionary measure.—*Gazette des Hôpitaux*, and *Edin. Med. Journ.*

GUYON'S "CEPHALOTRIPSIE INTRACRANIENNE."

M. Guyon claims (*Wiener Med. Press*, No. 20, 1868) that by making an additional perforation with the sella turcica, we secure greater compressibility of the head. He uses the following instruments: 1. A guiding-staff thirty centimetres long, seven millimetres in diameter, the lower end shaped like a screw-driver, the upper provided with a moveable handle. 2. Two trephines, which differ only in the size of their crown. One crown is three, the other four centimetres in diameter. Each trephine consists of a crown with simple saw-teeth, a hollow axis, which permits it to be pushed over the guiding-staff and a transverse handle. To guard against going too deep, the crown is provided with a short sheath. 3. A slender steel cephalotribe, which is only to be compressed with the hand; the handle of the right blade is provided with a moveable serrated plate (cremellaire), which fastens to a tooth on the handle of the left blade, and holds the handles together when they are compressed. The operation is as follows:—Pass the guiding-staff up under guidance of the fingers of left hand, and bore into the presenting cranium; then remove the handle, and push the larger trephine over the staff through the opening in the skull. This is easily accomplished; and we then withdraw both instruments. The operator now introduces his left hand, and with its index finger enters the opening in the fœtal cranium, and seeks the sella turcica: when found, the guiding-staff is led to it, and bored in as before. The smaller trephine is now pushed over the staff, and bored as deep as the protecting sheath will permit. The cephalotribe is then used in the customary manner. Of course, this operation can only be performed in head presentations. It has the recommendation of Professor Späth, of Vienna.

THERAPEUTICS.

TO PREVENT DEATH BY CHLOROFORM.

Experiments on inferior animals show that they may be restored from apparent death by chloroform, by the continuous galvanic current, the negative pole being put in the mouth and positive pole in the rectum. In some cases the animal was left for two minutes in a state of apparent death and then restored.—*Pacific Med. and Surg. Journal.*

FURTHER EXPERIENCE IN THE TREATMENT OF PHTHISIS PULMONALIS, &c., BY PANCREATIC EMULSION.

By Richard J. Kinkead, A.B., Lic. Univ. Dublin, L.R.C.S.I., & L.M.D.

(Continued from page 185.)

How comes it that pancreatic emulsion is retained and assimilated when cod-liver oil is not? In the paper before alluded to I stated that the pancreatic juice had alkaline properties, and so neutralized the excess of acid in the stomach; and, although Bernard has given his authority to the statement that the pancreatic juice is always alkaline, yet I believe there is reason to doubt the accuracy of the assertion. The following experiment was made in the pig-killing establishment of Mr. Harris, of Calne.

"On March 22, 1866, forty pigs were killed, and the pancreas of each examined immediately after death. The killing and examination of the forty pigs in succession occupied less than an hour. Litmus paper was applied to the interior of the duct and to the divided gland cells, and on being pressed sufficiently against the tissues to absorb moisture, the paper was in each case reddened where it was moistened."*

On August 3 Dr. Collins writes to Dr. Dobell, "As you requested, I have tried a series of experiments upon the pancreas parotid and sublingual glands. The two latter have a decidedly acid reaction, but the pancreas I'm not quite so certain about. In one batch of pigs killed in Buckinghamshire it was acid; in another lot in Hertfordshire, alkaline."†

It is therefore not on account of its alkaline properties that the emulsion is retained; indeed, we find that in an excessively acid state of the stomach it will be rejected; but, unlike cod-liver oil, the administration of an alkali before the meal after which the emulsion is taken, will in most cases overcome this difficulty.

The explanation I think is this—that the stomach is not the organ in fault, and that the emulsion is not affected by the stomachic digestion, but passes through unchanged to where the digestion of fats commences the duodenum. If the dislike to fats and the difficulty of their digestion depended solely on the acidity of the stomach, the administration of alkalies should set all right. But we find they fail to do so. This and the fact that cod-liver oil agrees for a certain (indefinite) time and then disagrees, points out that the evil lies somewhere beyond the stomach.

The stomachic digestion is mainly that of plastic food. The fault then must be either in the pancreas or in the mucous membrane lining the intestine.

Either the pancreas pours out an unhealthy secretion incapable of emulsifying fats and so preparing them for absorption by the lacteals or the secretion may be deficient; or, again, the absorbing surface of the intestine may be diseased and rendered incapable of taking up the emulsified fat by some independent disease. We know that in dysentery there sometimes occur "exudations into the pulmonary parenchyma, chiefly in the form of isolated deposits of considerable density disseminated through the substance of the lungs. These masses passed into a purulent condition, and, microscopically, they were composed of broken-up cells, granular matter, and pus elements.'* Does it not seem probable that these deposits may be tubercle? Or there may be a functional incapacity for absorbing fats, the lacteals being irritated by a viscous secretion, and improperly prepared fat passing over them.

What so likely to correct these faults as fat made into an emulsion by healthy pancreatic juice? It gives time for the pancreas to recover tone and become healthy. It affords to the functionally diseased lacteals a properly emulsified fat, and so reclaims them from their bad habit, and, at the same time, supplies to the system what is its chief want—oleaginous food. That the emulsion passes through the stomach unchanged is, to say the least, highly probable, from its having "remained complete after standing two days mixed with pepsine, hydrochloric acid, and water."*

---

* Dobell on Special Action of Pancreas on Fat and Stomach.

† Dobell op. cit.

* Aitkin's "Practice of dicine," vol. i., p. 511.

There is good reason for believing that fluid oils may be taken up by the blood of the portal system; and this furnishes a probable explanation in those cases in which cod-liver oil is for a time retained by the stomach. But this mode of ingress for fatty food may be, after a time, stopped up, perhaps from repletion, and the stomach, acting as porter to the system, will not retain food that there is no demand for.

But there is yet another class of cases in which cod-liver oil agrees, in which the oil is digested, and yet the progress stops at a certain point, and the patient sooner or later declines again.

A rational explanation of this is "that not less than two ounces of fat per day on an average is required to keep up healthy nutrition in an adult. We have next to bear in mind that, before a case of consumption ordinarily attracts attention and begins to be treated as such, many pounds' weight, principally consisting of fat, have been gradually removed from the body. In this condition—1. A deficiency of fat through the organism. 2. A loss of power to assimilate ordinary fats. 3. A constant demand for two ounces per day to maintain healthy nutrition. We administer cod-liver oil in the belief that this form of fat will assimilate, when other forms will not. Supposing that it agrees, and that some or all of it is utilized, a rapid improvement takes places in the patient, from the supply of some of that for want of which life was steadily fading." "But there are very few persons who can take more than from half an ounce to one ounce of oil per day—few who can take this steadily from week to week without intermission. But supposing an ounce or an ounce and a half per day to be taken regularly, how is this to supply, not only the two ounces per day required for healthy nutrition, but all the extra ounces of arrears that were lost before the treatment was begun? But, assuming the possibility of two ounces of oil for nutrition and another two ounces for arrears being taken and utilized, even then the *whole thing may be unstable and may break down*, from the fact that we are supplying oil and not *solid fat*: a body rich in olein and poor in stearin and margarin; in the place of bodies, rich in stearin and margarin and poor in olein—such as the fats taken in normal food."†

"The importance of pancreatic emulsion of solid fat over cod-liver oil in the treatment of tuberculosis must be as great as that of supplying a plant with good soil instead of putting it into water. In the one case a provision is made for the maintenance of normal life; in the other, death is only postponed by a temporary expedient."‡

But, after all, the true test of the value of a remedy is experience of its effects. If we see it prove of undoubted benefit in a succession of cases, and especially where other remedies have been of little or no use, and if the improvement that follows its use is not a mere temporary one, a sudden flickering up of the expiring flame of life, but a steady, progressive, permanent one, then it is probable that the theory on which it is put forward is correct.

It is necessary, however, to avoid considering a medicament which is of great value as a new form of, or rather in any form, as an elixir vitæ.

The following cases, treated by pancreatic emulsion, demonstrate its value, not only in phthisis, but in other affections caused or attended by a low state of nutrition and a poor condition of the blood.

C. G., (whose case I reported in the MEDICAL PRESS AND CIRCULAR of Feb. 26, 1868,) having exposed herself to wet and cold, got a relapse. I was sent for to see her 29th of March. She had slight spitting of blood, night sweats, pulse about 80, breathing slightly interrupted under right clavicle, expiration slightly prolonged, bruit in subclavian. Ordered pancreatic emulsion, in ʒii. doses, twice a day, to be taken one hour and a half after dinner and supper. Also ℥ss. of a mixture of ol. morhuæ, ℥vii. syr. ferri iodidi, ʒi. in the morning and an hour before supper. She gradually improved till the 21st of April, when she was seized with a slight attack of rheumatic fever; the chest signs, too, were worse. On the 27th slight hæmoptysis, but otherwise better. On 29th, dose of emulsion increased to ʒiij. On May 4th, physical signs better; general symptoms improved. On May 25th I saw her for last time; she was greatly improved. She steadily progressed, and has, up to the present date, continued in perfect health.

J. M., railway porter, suffering from aneurism. Sharp hæmoptysis, purulent expectoration, night sweats. Confined to bed. Has taken cod-liver oil, which did "some good." Began the emulsion in ʒii. doses. In a week he was able to be up and about; in a fortnight more he returned to his work, the station-master setting him to light duty. At this time I got him weighed. His increase for three consecutive weeks was—1st week, 4 lb.; 2nd week, 1¼ lb.; 3rd week, 1 lb. He regained his colour and strength; his appetite improved, and he picked up flesh. He died suddenly in October from the aneurism bursting. He began to take the emulsion at the end of March or the beginning of April, at which time he was in a very low, almost a dying, condition. He was enabled, by the use of the emulsion, to attend to his business, and was a comparatively healthy man till his death, nearly seven months afterwards.

B. R., ætat 20, male. Very tall and thin; dark complexion. Eldest brother died of acute phthisis. Had a bad cough last winter, which got better towards summer, but never entirely left him. Cough worse within last few days. Can't *eat fat meat or fat of any kind.*

August 31st.—Cough very bad; headache; face flushed; pain in side; expectoration scanty; sweats at night; dulness under right clavicle, the rest of chest clear, on percussion; respiration interrupted under right clavicle; sibillant râles over both sides of chest; pulse hard and rapid. Ordered, tr. verat. virid. ʒiiss. in emuls. amygd. ℥viii., ʒi. teris horis, emplast. sinapis to chest, to inhale steam of boiling water.

September 1st.—Cough easier. Sputa purulent and nummular, floating in a rusty-looking watery expectoration. slight pectoritoque under right clavicle; minute crepitation in lungs on both sides, posteriorly; râles not so loud; respiration tubular in parts; inspiration and expiration equal. Ordered continued mixture, beef-tea, and wine.

September 2nd.—Posterior and lower portion of right lung solidified; slight friction sound. Painted side with lin. iodi; purgative of calomel and jalap.

September 3rd.—Side better; friction sound on left side. Applied lin. iodi to both sides. Crepitus less; râles continued; expectoration purulent, tinged with blood. ℞ iod. kali, gr. 80; liq. cinch. ext. tarax., liquid aa. ℥i., tea-spoonful three times a-day.

September 5th. — Dry friction sound on left side. Emplast. littæ.

He improved till the 10th, when he was not so well. Pectoritoque very distinct under right clavicle; breathing tubular on right side; dulness under right clavicle. Ordered ʒii. doses of pancreatic emulsion.

September 12th.—Emulsion agrees with him. Better. Respiration natural, save in the right subclavicular region, where there is still some pectoritoque; expectoration less, but still purulent; night sweats less; pain in side (pleuritic stitches) nearly gone.

From this date he progressed favourably, and is now apparently well—"stouter than ever he was." He could not take cod-liver oil or fat of any kind, but experienced no difficulty in taking the emulsion. The habits and position of life of this patient were much against his recovery. The ceiling of the room he slept in was so low that I could touch it with my hand, and it was not more than 8 feet by 10 in size, and, besides his own, there was a large bedstead, with a top to it, in the room, in which some other member of the family slept.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,

Deputy Inspector-General of Hospitals.

DYSENTERY (*continued*).

There is, perhaps, no disease in the treatment of which absolute rest is more necessary than it is in dysentery, and certainly there is none in which removal by such means as in India are commonly employed for transport of the sick is so likely to be injurious. This is so evident when we consider the nature of the tissues involved that I need not in this place further dwell upon it than to remark that the discomfort, jolting, and necessary exposure, not alone on field service, but on an ordinary march, act most injuriously upon persons affected with this disease; and that, however great may be the benefit obtained in many cases of disease from rapid change and the jactitation inseparable from travelling in that country, it is essential that the patient labouring under dysentery be not removed until the active stage of the malady has subsided. In those cases where the affection has become chronic the conditions are altogether different. The wonderful effect for good exerted in them by removal, more especially if it be to sea, is well known to all officers of experience in the treatment of tropical diseases.

I have already alluded to the prevalence, in the lower parts of Bengal, of the hæmorrhagic form of this affection. In the majority of stations further inland, where the soil is more arid and the atmosphere less humid, the inflammatory is the more common; but persons debilitated by fever, insufficient food, or by more length of Indian service, not unfrequently become the subjects of the former even there. It has, moreover, been found that the rate of mortality from dysentery has always hitherto been greatest during periods when fevers prevailed in an endemic form.

The experience of 1857-8 induces me to believe that a soldier attacked with severe dysentery on the march must almost to a certainty die from the disease unless it be practicable to at once give him the advantage of being left in a stationary hospital. Men affected with mere trivial attacks of diarrhœa, if arising from irritation of the intestinal canal, often have that malady converted first into inflammatory dysentery, and then into hæmorrhagic, by the continued jolting in a dooly on successive long marches; added to which the exposure to chills, to which they are subject when obliged to attend to the calls of the disease during the night, and in the cold morning air while on the march, are of themselves most injurious.

I have already given cases in illustration of the two forms of dysentery most frequently met with in India. In both extensive disorganization of the large intestines was present; and indeed it is difficult to believe in the occurrence of a case of dysentery in which there is not destruction of tissue to some extent at least. That such are not altogether wanting, however, is indicated in that which follows, its subject having, no doubt, by the exposure and fatigues he had undergone, been reduced to a condition of body in which the tone of his tissues and functions generally were much lowered.

Private Patrick Drennan, 10th Regiment, aged thirty-two years; thirteen years in India; admitted, August 22, 1857; died, 27th; under treatment five days. Came in from Jugdespore, where he had much exposure, fatigue, and wet. Six days previous was seized with severe purging of blood, after having been wet all night. Had to march every day, and on arriving at Dinapore was much exhausted; skin clammy and cold; pulse feeble and soft; purged every few minutes, the blood trickling away as he went from bed to stool. Quinine, three grains, and opium, one grain, every hour; chloroform to abdomen. The flux continuing, he, on the night of the 24th, had gallic acid and quinine, each five grains, opium two grains, every hour; turpentine fomentations and turpentine enemata. These moderated the purging, but he has prolapsus ani from straining. He had dysentery on two former occasions, first in 1846 and in 1854, but in neither so severely as now. On the morning of the 26th improvement had taken place; he felt more comfortable, and was somewhat less often purged; hæmorrhage ceasing, continue medicines. It would appear that the improvement was but temporary. The flux continued unchecked by the use of medicine; on that night the frequency with which he was purged increased; the evacuations were pure blood. On the 27th there was very copious discharge of fluid blood, and he rapidly sank and died.

The *post-mortem* appearances in this case were:—Liver healthy; bowels pale and bloodless; colon tinged internally with partially coagulated blood.

The notes of this case distinctly state that examination failed to detect the presence of ulcers within the colon, or other disorganization of the intestine. We are therefore forced to believe that, however rare such instances may be, yet that under certain conditions fatal hæmorrhage may occur by exosmosis of blood through the mucous membrane, and without the presence of ulceration.

Subsequent experience induces me to believe that in cases not only of inflammatory dysentery, but in those of the hæmorrhagic type of the disease, enemata of hot water repeatedly administered are not only highly to be recommended as means of treatment, but that they afford an amount of relief to the patient that by no other means can be obtained. I do not mean by this the repeated introduction of long enema tubes, such as were some years ago in common use in India, but the administration of lavements in the ordinary manner. Nor can I too strongly urge the great benefit and relief derivable from the very simple means of permitting patients affected with dysentery to sit upon commodes containing hot water. The vapour soothes the pain of straining in a manner that nothing else does, and thus, no doubt, becomes a powerful means of cure. One other remark on treatment I would here make. It is to recommend in those terrible cases of hæmorrhagic dysentery, such as I have described, that, where gallic acid fails to check the flux, a solution of alum with diluted sulphuric acid added, or of acetate of lead with acetic acid, should be tried. But let us hope that, with improved sanitary conditions among our troops in India, such forms of disease as have been just described shall for the future only occur in rare and exceptional circumstances.

Some years ago a translation of a book by Dr. Bleeker, of Batavia, appeared in the Indian "Annals of Medicine," and attracted much attention. According to that author the early stage of hæmorrhagic or, as he called it, malarious dysentery, consisted in hyperæmia and retention of blood in the mucous and submucous tissues, indicated in the first instance by mucous and muco-sanguineous evacuations; then by the deposit of exudation beneath and in the mucous membrane of the colon, indicated by hæmorrhagic or chocolate-coloured evacuations.

According to Morehead, the most striking effects in restraining the discharge of hæmorrhagic dysentery were obtained from the practice of Dr. Leith. This consisted in administering gallic acid in doses of eight grains, with a couple of drachms of tincture of catechu every hour and a half, port wine being at the same time given freely. This plan was, with many others, tried in the 10th Regiment, but, unhappily, without the success attributed to it by the author named. Quinine is frequently used, and it is stated with considerable success, in the treatment of the hæmorrhagic form of dysentery, more especially in Batavia, Rangoon, and in fact wherever in India malarious influences prevail with great intensity.

In the early part of these remarks, I mention the circumstance that the disease in the 10th Regiment prevailed to the most fatal extent during seasons when fevers affected the men to an unusual extent, and also when the soldiers were subjected to great atmospherical change, and debilitated by severe duty and exposure. I cannot, therefore, better conclude this portion of the subject than by quoting the statement of two eminent authorities, whose expressed opinions are fully corroborated by my own personal observations. Dr. Watson, in his work "On Practice of Physic," states "that whatever gorges the splenic vein gorges its tutelary, the inferior mesenteric, which carries the blood from the colon and rectum; before such congestion of the mucous membrane, inflammation is engrafted, and in this way (indirectly) dysentery may be said to result from marsh effluvia. Ague is an effect of malaria, and dysentery is sometimes a sequel of ague. In precisely the same way dysentery is apt to supervene in hot climates upon hepatic congestion and disease."

Annesley looks upon dysentery as often caused by exposure to night air, and believes it to prevail most at stations characterised by great heat and moisture during the day, and cold dews at night.

When dysentery passes into the chronic form, not only is the health of the person so affected seriously jeopardised, and recovery always distant and uncertain, but accession of the symptoms in an active form is at all times liable to occur from exposure, whether by accident or carelessness to the ordinary causes of intestinal disorders. Patients thus affected are not now ever retained in India, but are sent either to England or to the continent of Europe, with the view of restoration to health. Of the nature of attacks from which men and officers thus sent home are liable to suffer even a considerable time after leaving India, the following case is a fair illustration, and considering the importance of my present subject to army medical officers, I trust I may record it, although not strictly within the sphere indicated in the title of these papers.

W. C. L. had been in England a year, having been invalided from India in consequence of dysentery. Had suffered on several occasions since his return to this country from accessions of that disease, and in the early part of Nov. 6, 1859, had an attack of greater severity than usual. He was then quartered with his regiment at Newbridge, and having been recommended to proceed to his friends at Brighton, left Dublin by one of the Irish steamers. The weather he experienced on the passage was boisterous, and the consequence was that his condition became so alarming, that on the arrival of the vessel at Plymouth, he had immediately to be landed. This occurred on 20th Dec. following, at which time his condition was thus described: —He was suffering severely from abdominal pains; the limbs and body were cold; he had constant retching; was purged every ten minutes or so, passing small quantities of clear jelly-like matter, slightly tinged with blood; straining was very severe. He immediately on being seen had chloroform, ♏ x. in a little soda-water; a sinapism was applied to the abdomen. An enema, consisting of tinct. opii, ʒss. in one ounce of starch was administered as soon as possible, and he was directed to take every second hour a pill composed of pulv. Jacobi, grs. ij.; opii, gr. ss.; pulv. ver. capsici, gr. ss.; kino, gr. i.

He obtained some degree of relief in the course of the night, and the report of his state on the 21st mentioned that he was not worse than on the previous evening. The vomiting had been checked, purging was attended by less suffering, the evacuations were less slimy than they had been, but had the characteristic dysenteric odour, the tongue was thickly coated with grey fur. He was now ordered in addition to the former pills, which were to be continued, those composed as follows—one every six hours—namely: Pil. hyd. et pulv. Jacobi, aa gr. i.; extracti gentianæ, gr. ij. The only nourishment he was allowed was milk. On the evening of the 22nd, at his urgent request, he was permitted to have a little coffee. On the 23rd he was very weak, but he described his own sensations as being decidedly improved. He had slept several hours at intervals, and the abdominal pain, which for some time had continued to recur in paroxyms, was now much diminished. The medicines were steadily continued.

On the evening of the 25th he vomited a little liquid, which, although not coloured by bile, was described as being bitter to the taste. During the early part of that day he had taken more fluid than usual. Was purged about every second hour; the evacuations liquid, fœcal, but containing some streaks of blood. The bladder sympathised with the irritation in the rectum. Occasional paroxysms of severe pain recurred in the abdomen. The tongue continued much coated, but the tip showed some slight tendency to clean. Pulse 88, of moderate strength. The treatment to be strictly continued.

On the morning of the 26th he was much in the same condition. He had been moved every two hours; the character of the evacuations as on the previous evening. In addition to the abdominal pain, which still occurred in paroxyms, he now complained much of severe spasms affecting the lower jaw and neck. He was very weak. Tongue as on the former day, and yet he expressed himself as conscious of his own sensations being still further improved. He was now directed to take one of each of the pills already ordered every alternate two hours.

On the evening of that day the tongue had begun to assume a more distinctly moist appearance than it had hitherto presented. The purging and other symptoms were as last described. The treatment was therefore persisted in.

On the morning of the 27th, the improvement in the state of the tongue had not advanced. Thirst, which had from the time when he was first seen been urgent, was now less so. The urine was high coloured and scanty. Considerable tenderness existed over the region of the bladder. He had slept tolerably well during the night, and purging was somewhat less frequent than it had been. Evacuations had become still more fœcal than they had been, and the mucus in them had decreased in quantity. There was no general tenderness of the abdomen, nor did that feeling of *bogginess* exist, which, to the experienced touch, is perceptible in advanced stages of this disease. The paroxysms of sickness and pain, although not entirely ceased, had become much less severe, and the spasm affecting the muscles of the jaw and neck had altogether ceased. The pulse continued at 88, with moderate power. The spirits were improving, as were also the patient's sensations as to his own condition. Medicines continued.

On the morning of the 28th, a very distinct improvement was recorded to have taken place. The tongue was cleaning, and was moist. The evacuations were less frequent, were voided with less suffering than previously, and were still more distinctly fœcal. The irritability of the bladder had also diminished. The medicines still to be continued.

In the evening of that day he was found to have been more frequently purged, although without pain. The evacuations were fœcal, but very offensive. He was directed to omit the use of his former medicine, and to substitute the following, namely—pulv. catechu., gr. ij.; opii gr. ss.; pulv. Jacobi, gr. i.; ex. gent., gr. ss., in pill; and a mixture composed of æth. chloric. m. xv.; spt. ammon. aromat., m. xv.; in ordinary chalk mixture flavoured with syrup of orange peel. One of these pills and a dose of the mixture were directed to be taken after each evacuation.

The morning report of the 29th states that the diarrhœa had been checked, although the character of the evacuations continued much what they were on the previous day. The irritability of the bladder had also diminished, but the spasms in the neck (trismus) had become more severe than they had been since their first occurrence.

The medicines last prescribed were omitted, and he reverted to the use of the first ordered forms of pills.

During the 30th, the state of the bowels had slightly improved. The trismus had given way. The evacuations were less frequent, but still fœcal. The medicine was continued.

On the morning of the 31st he was very much better. He had enjoyed a good night, having only been moved four times. The evacuations unchanged in character, save that they contained a little mucus. Throughout that day the bowels continued to be moved about every second hour; the evacuations at times tinged slightly with blood, but in other respects unaltered in character. The straining and abdominal pain were both less severe than they had been, but there was considerable irritability of the bladder.

During the forenoon of 1st January, 1860, the diarrhœa had increased, in so far as the amount voided was concerned, although not in the frequency of the evacuations. The proportion of blood voided with them had increased, but portions of the evacuations were semi-consistent and fœcal. The trismus was less urgent than it had been, but a considerable degree of *rawness* was complained of along the course of the transverse colon. A cataplasm, with some mustard, was applied; the pills were omitted, the mixture continued, and he was directed to take every three hours one of the second description of pills that had been ordered, namely, those containing ½ grain of opium, catechu, grs. ii., and capsicum, gr. i.

On the evening of the 2nd an improvement in his condition was again reported; the tongue was cleaning and moist. He had not been much moved during the night; there was no thirst; trismus was less urgent; pulse 80, soft; and he for the first time relished a small piece of toast with tea. He was directed to continue the pills last ordered, and the mixture.

The notes of the case state that from this time to the morning of the 6th he continued as above described; the frequency of his evacuations gradually decreased, the tongue became cleaner, he felt a little appetite, and in all respects progressed favourably. On that date, however, a slight accession of diarrhœa took place. The evacuations were of a dark clay colour, and yeasty in appearance, unmixed with blood, but offensive. A dose of fifteen grains of confection of senna, fifteen of carbonate of magnesia, with tincture of ginger and aromatic spirit of ammonia, was administered, and with much benefit.

On the morning of the 7th, the notes of the case recorded that the evacuations had become more natural in character, and had diminished in frequency. The pills of the 1st were therefore re-ordered. From that date he progressed so favourably that on the 8th the astringent mixture was omitted. On the morning of the 9th he stated that he had only been moved at midnight and again at eight a.m. The evacuations were liquid, fœcal; sensations natural, and tongue clean. He now expressed himself as very hungry. He was therefore considered to be convalescent. The pills were ordered to be continued as before. The diet was and had been entirely farinaceous.

From the above date improvement was progressive, and on the 30th he proceeded to his relatives at Brighton.

This case I consider illustrative of the nature of attacks to which, for a considerable time after their return to Britain, persons who have suffered from the acute form of the disease in India, are liable. It is, moreover, valuable as illustrating the various phases assumed by such attacks, and, I think, of the means by which these are to be best combated.

(To be continued.)

Petroleum and Scabies.—A. P.: "Please inform me in what manner petroleum should be used for the cure of itch or scabies, and whether crude or not." It may be mingled with any mucilaginous or unctuous substance, as mucilage of gum arabic, olive oil, &c. The crude will answer.—*Health Reformer.*

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

Monday, February 15, 1869.

Dr. B. W. Richardson, F.R.S., President, in the Chair.

Mr. **Coles** exhibited two polypi, removed from the rectum by an operation rendered painless by ether-spray.

Dr. **Thompson** adduced a case showing that success in the prevention of pain is not always attained. This was corroborated by Mr. **Coulson**.

Dr. **Anstie** pointed out the great difference in sensibility between the skin at the verge of the anus and the mucous membrane higher up. The former required the profoundest influences to deaden its sensibility.

Mr. **Mason** thought that ether-spray was but seldom successful in these cases.

The **President** said that ether-spray in these cases certainly did not present unequivocal advantages. Some cases succeeded admirably; others failed. Two things are most important: first, a tube which does not use large quantities of ether; secondly, a pure anhydrous ether, having no acid reaction.

Further remarks were offered by Dr. **Camps** and Mr. **Marshall**.

Dr. **Greenhalgh** exhibited—

SOME NEW MEDICATED PESSARIES AND SUPPOSITORIES,

the basis of which (isinglass and glycerine) offered many advantages over the fatty and saponaceous compounds hitherto used.

Dr. **Meadows** agreed that fatty bases were unavoidable, as the vagina does not absorb fat. He had tried the fluid pessaries introduced by Dr. Sansom, and was inclined to prefer them to all others.

Dr. **Anstie** read a paper on—

THE POPULAR IDEA OF COUNTER-IRRITATION.

His own views presented a very complete though undesigned coincidence with those propounded by Dr. Dickinson in a late number of the "St. George's Hospital Reports." As to the value of counter-irritation in medical practice, proof is singularly deficient, and we are unable to explain the rationale of the process. The term itself is almost a relic of barbarism, of the times when the human body was supposed to be ruled by intestine demons. The author passed in review the various structures which could be possibly influenced by the process known as counter-irritation.

1. The Blood-vessels.—These could only be affected within a narrow range. In the case of counter-irritation of joints, the operation might be explained on account of the connection of the superficial with the deeper vessels, and consequently the depletion of one being the depletion of the other; but in the case of counter-irritation of the chest for the possible relief of an internal congestion, no such explanation can be given.

2. The Nerves.—The difficulty here is the fact, taught by ordinary experience, that peripheral irritation is more productive of morbid than of beneficial results.

3. The Absorbents.—Here the action must be almost wholly a bad one. The author condemned the routine practice of blistering. The foundation of it was too often the lingering love of something like a charm.

Dr. F. **Simms** thought that Nature herself taught lessons of the value of counter-irritation when in an agricultural labourer suffering from internal congestion she induced a crisis coincident with a belt of shingles. Lepra, too, was sometimes a Nature's counter-irritant.

Mr. **Braine** supported the plan of counterirritation on his own experience, and in practice tried upon himself. He had suffered from injury of the knee, and was thus subjected to great pain. The actual cautery was applied at a white heat; the procedure gave little pain at the time, but led to immediate relief and ultimate recovery.

Dr. **Sansom** believed there was a danger of our becoming too iconoclastic. The practice of centuries should not be lightly cast aside. Science taught us that slight peripheral irritations might produce profound internal effects—witness the phenomena of epilepsy. It is impossible to draw a line between the vascular and nervous system as to the extent of their implication. A cutaneous counterirritant acts on multitudes of minute ganglia and nerve fibres, surrounding capillary blood-vessels, and in direct relation with the like nerves of more distant blood-vessels. He felt that the evidence of experience in this question was too direct to admit of doubt—it was rather to be hoped that investigators would demonstrate the obscure links of the causes of the phenomena than that they should at once abandon a method which they cannot wholly explain.

After some remarks by Mr. J. W. Barnes,

Dr. **Cholmeley** thought that in the medical world there obtained the converse of that process of rehabilitation which is common in the literary world. He defended counter-irritation, and was convinced of its value, especially in cases of ulcer of the stomach.

Mr. **Weeden Cooke** adverted to the plan of treating diseases of the joints by blisters distant from the seat of morbid action. The *modus operandi* could be explained on the principle of one disease (induced) relieving another.

Mr. **Watson** admitted the practice was empirical; he considered when counter-irritation is employed in a severe degree it is hurtful, but when in a mild degree it is beneficial. The sequelæ of burns showed how strong an influence peripheral impressions have upon central actions.

Mr. **Dunn** inquired what is the effect of vesication upon the pulse?

Dr. **Webster** supported counter-irritation on the ground of practical experience.

Dr. **Symes Thompson** agreed with the author as to the impolicy as well as the cumbrousness of the word "counter-irritation. He nevertheless supported the practice; the skin is a great nerve-expanse, offering greater facilities for therapeutic action that even the stomach itself."

Dr. **Broadbent** said the plain question was—Do so-called counter-irritants do good? On the ground of objecting to any term which one does not understand, he agreed in condemning the term. He certainly believed in the good effects of warm fomentations, &c.

Dr. **Camps** thought that the explanation of the action of nearly all remedies was in the fact of their being counter-irritants.

This view was also held by Mr. **Gregory Smith.**

The **President** thought that the term was good if the facts were good; the author's arguments seemed intended to shake the foundations of the *practice*. Much harm had been done, especially in phthisis, by injudicious irritation of the skin. In some cases we must accept what we cannot explain. Who can doubt the value of blistering in obstinate ulcers of the legs? He confirmed the observations made as to the powerful agency of external impressions, instancing the observations of Weir Mitchell, confirmed by himself, showing that the stage of thawing of the skin after freezing in the neighbourhood of a portion of the encephalon was attended by the same symptoms as freezing the portion of the encephalon itself. There is an intimate and constant relation between the skin nerve and the encephalic centre.

Dr. **Anstie**, in the course of an able reply, repudiated the notion that he desired to condemn all agents known as counter-irritants. He wished to render them "arms of precision." He had seen danger directly follow from the unrestrained practice. A blister does not equalise the pulse, it aggravates the febrile form of the pulse-trace.

THE ARMY MEDICAL CHIRURGICAL SOCIETY OF PORTSMOUTH.

Feb. 3, 1869.

Deputy Inspector-General Dr. **Gordon**, C.B., in the Chair.

Assistant-Surgeon **Power**, 2nd Bat. 13th Light Infantry, read a paper on

THE TOPOGRAPHY OF THE MAURITIUS IN RELATION TO THE EPIDEMIC OF MALARIAL FEVER OF 1867.

He observed that the island presented a central elevated plateau, irregularly surrounded by detached hills, the remains of an old crater wall; that its northern part was irregular, broken into a series of small ridges and valleys, its soil thin, and its surface much covered with basaltic rocks. Towards the south the island presented a succession of mountains and spurs of hills, and everywhere the land sloped more or less irregularly towards the sea, a belt of coral, thickest towards the southern end, almost entirely surrounding it. Forests now only exist in a few of the upper districts, having within recent times been in part destroyed. Rivers run chiefly on the windward side, and the prevailing rock of the island is columnar basalt, the whole apparently still undergoing a gradual process of upheaval. The soils are of stiff ferruginous clay, especially in the middle of the island and near the hills: in other places it is of a dark slate colour. To the leeward there is much flat marshy ground, charged with organic matter. He entered into particulars regarding the meteorology of the island, and observed that the districts where fever most prevailed were on the leeward side of the island, and where, under ordinary circumstances, the greatest rainfall took place. He observed that, until within the last few years, no marked malarial fever was known in Mauritius, indeed, less than occurred in the fenny districts of England. The chief characteristics of the hot season of 1866-7, he observed, were—1. An absence of rain in the proper rainy season. 2. Greater and more continued heat than usual. 3. The absence of the usual electrical phenomena, as thunder and lightning, and, 4. The absence of cyclones. There was thus a comparative state of stagnation of the atmosphere, the breezes that did prevail being only local in their nature. He observed that high temperature and an absence of rain, acting upon soil saturated with organic matter, were the existing causes of the fever; many of the parts left dry having heretofore been always covered with water, and the temperature being further raised by the circumstance of the sun's rays being absorbed and retained by the thinly covered basaltic rock. He believed that this view was confirmed by the fact that those parts where the greatest rainfall occurred, and where the soil was moist, were free from the fever which elsewhere prevailed.

Enteric fever is not as a rule, he thinks, recognized in the Mauritius, and that where, in 1867, it did occur, it was due to typhoid poison, and not to malaria.

Assistant-Surgeon **Alcock**, 35th Regiment, then read a paper on

THE INFLUENCE OF NERVOUS POWER IN CONTROLLING THE TEMPERATURE OF THE BODY.

Starting with the theory that "the blood itself is the seat of those chemical changes that develope force in the body," he alluded to the mechanical part played in the development of heat by the dilatation or contraction of the capillaries.

To exemplify the direct influence of the nervous centres over the metamorphosis of tissues, he instanced the six-fold increase of urea in the urine of the rutting ram, as noted by Professor Haughton.

He then reasoned that præternatural heat was the result of three conditions—suspension or exhaustion of the functions of the sympathetic, diminished nutrition, and increased metamorphosis—but he believed the second and third to be consequences of the first, and brought forward heat apoplexy as a disease in every way typical of an exhausted sympathetic; in support of which he showed that in ten out of eleven cases of this affection which occurred in the 35th Regiment in Mooltan, there was a distinct history of previous nervous exhaustion from fatigue, intemperance, or disease. In conclusion, he laid before the meeting the thermometric record of a case, in his own practice in India, in which uterine hæmorrhage caused temporary paralysis of the right half of the body, with lowering of the temperature of that side. Fever supervened, and then the temperature on the paralyzed side rose considerably above even the fever heat shown on the sound side.

A case of

CALCULUS IN THE BLADDER,

reported by Surgeon **Porter**, 97th Regiment, was then read.

A native of India, aged 22, applied to Dr. Porter for relief from a large vesical calculus, whose presence was readily detected. In addition to the ordinary symptoms of stone, there existed a fistulous opening in the right lumbar region, evidently connected with the kidney, through which passed urine, pus, and "gravel." The lateral operation was performed, and, after considerable difficulty, the calculus extracted. It was found to consist of the triple phosphates, and weighed three ounces and four drachms. The health of the patient rapidly improved, the fistula in the lumbar region closed, and in six weeks after the operation the man returned to his home.

SURGICAL SOCIETY OF IRELAND.

(Continued from page 164.)

OSSIFICATION IN THE RIGHT GLUTÆUS MAXIMUS MUSCLE.

Dr. Bookey presented a specimen taken from a subject in the dissecting-room of Dr. Steevens' Medical School, in the month of November, 1868. The subject was a very muscular man, aged 65 years, and six feet high. On taking the integuments off the right glutæus maximus muscle its lower third was raised; on examining the raised portion of the muscle, a bone could be felt deeply imbedded and covered by the muscle, descending obliquely outwards and forwards from the right side of the sacro-coccygeal articulation towards the base of the great trochanter of the right femur. On raising the glutæus maximus it was found to be attached to the inferior surface of the bone. The bone itself is seven inches long, somewhat like a rib, only thicker and rounder; its convexity looked backwards, its concavity forwards, and its surfaces upwards and downwards. The head of the bone is attached by means of ligaments to the right side of the sacro-coccygeal articulation; it is also attached to the great sacro-sciatic ligament, and could easily be felt on introducing the finger into the rectum. The body of the bone arched over the great sciatic nerve, and terminated, rounded and pointed, on the posterior inter-trochanteric line, near the base of the great trochanter. This extremity of the bone is enveloped in a bursa, and also attached to it, by means of ligaments, is a smaller bifid bone, intimately related to the tendon of the glutæus maximus muscle. On placing thin sections of both bones under the microscope the bone-cells and Haversian systems were seen well-developed. On examining the other muscles of the subject no ossifications were seen, save a small speck on the tendon of the left sub-scapularis. The insertion of the left deltoid was ossified for about half an inch. The normal sesamoid bones were largely developed. The lesser sacro-sciatic ligament on the left side was almost completely ossified, the great one slightly so. On the right side the great sacro-sciatic ligament was ossified for about half an inch, the lesser one was free from ossification. The other ligaments were normal. On the first rib on the right side there was an osseous tumour, which was united by ligaments to a similar tumour on the second rib. On the bodies of the last lumbar vertebræ, and on the second bone of the sacrum, small osseous deposits were found. The coccyx consisted of three pieces, and its articulation with the sacrum was quite movable. There were the normal number of ribs on both sides. Neither the integuments of the glutæus maximus muscle nor the muscle itself presented a trace of inflammatory thickening. This may be due to the movable condition of the bone, so that, taking into account the ligamentous connections of the bones, the other ossified ligaments, and the bony tumours, also its microscopical structure, it may be regarded as a case of true ossification in the glutæus maximus muscle, and not anything of homological interest in comparative anatomy.

HOUR-GLASS CONTRACTED STOMACH.

Dr. W. Thornley Stoker laid before the Society a specimen which he had recently removed from the abdomen of a female subject lying in the dissecting-room attached to the College of Surgeons. It was an instance of a peculiarly rare and interesting condition of the stomach—namely, the division of that organ into two portions, a right, or pyloric, and a left, or œsophageal, pouch. The entire length of the two parts from right to left was rather more than twelve inches, and they were obliquely situated in the abdomen, the left being most superior. The œsophageal division, which was more or less globular in form, was the larger, having a capacity of thirty-four ounces; whilst the right portion, which somewhat resembled the usual form of the viscus, held but twenty-five ounces of water.

The constricted part between the two was about an inch in length by three-quarters of an inch wide, and had a peculiar twisted appearance, which became less apparent when the left pouch was distended, and which Dr. Stoker conceived might have acted as a valve, by so untwisting and opening the passage from one cavity to the other. It was surrounded by a tendinous structure, into which the longitudinal fibres of both sides appeared to be inserted, and which extended for more than an inch on to the stomach on either side, being longer above, behind, and in front, than below. The stomachs appeared to join obliquely, the plane of their junction running from before, backwards and to the left, and being surrounded by the tendon completely, as the muscular fibres of one side were not continuous with those of the other.

On examining the interior of the organ, the mucous membrane, which was too old for microscopic inspection, seemed to possess the usual appearance in all its extent. No valve existed at the constriction, which was sufficiently large to give passage to the thumb. The pyloris was well-developed, but smaller than usual, and the œsophageal opening, which was situated at the upper and back part of the left cavity, presented no peculiarity.

The pyloric division possessed coats of a greater and more even thickness, whilst those of the left side were thinner and of more variable strength. The muscular fibres, which were developed to a most extraordinary extent, consisted of two sets, the outer longitudinal, the inner oblique or circular. The superficial fibres of the left side were continuous with the longitudinal fibres of the œsophagus, and ran along the superior and inferior borders of the organ as far as the tendinous structure, into which they were inserted, being also thinly distributed over the anterior and posterior surfaces, and being so thick and red along the upper edge of the stomach as to resemble voluntary muscle. The corresponding fibres of the right side were continuous with the longitudinal bands of the small intestine, and ran, as did those of the left, principally along the borders of the sac, and to some extent on its surfaces, being also like them inserted into the tendon. On removing a portion of this coat the deep fibres could be seen, running on both surfaces of both pouches in the same direction—viz., downwards and to the right side.

The greater and lesser omenta were attached along the lower and upper borders respectively of both the stomachs, and the gastro-splenic omentum was connected to the left side of the œsophageal cavity.

The arteries presented some modifications; the gastric and pyloric took their usual courses, one running to the right and the other to the left, neither arriving at the constriction, but stopping short without anastomosing, and distributing themselves to the surfaces of their respective divisions. The splenic sent the vasa brevia as usual to the extreme left of the stomach. The gastro-epiploica dextra and sinistra ran along the inferior borders of the right and left divisions, and anastomosed freely at the constriction, the only anomalous condition being that the latter came off from the left phrenic instead of from the splenic artery.

A careful examination showed that no abnormal condition existed in any other part of the intestinal tract, excepting that the duodenum, which crossed the spine in its usual situation, was somewhat larger than it generally is. As far as he (Dr. Stoker) could ascertain the history of the case, the woman, who was forty-three years of age, and who had been an inmate of the North Dublin Union, had died from lung disease, and had shown no symptoms referable to the state of her stomach.

There were some old adhesions in the abdomen, but nothing more than is seen in the great majority of subjects. There could be no possible doubt that the condition of the stomach was congenital; but to enter upon its true explanation—to discuss whether it was merely a division of the stomach into cavities, whether it was a true case of double stomach, or whether, on the other hand, it might not be an exaggeration of that condition described by Luscha as the spindle form dilation of the œsophagus—was forbidden by the rules of the Society in exhibiting a recent specimen.

Struthers has described a somewhat similar case, but it differs from his (Dr. Stoker's) in that no mention is made of the peculiar muscular development, of the twisted neck, or of the tendon surrounding it. The same writer mentions a number of authors who have referred to a bilocular condition of the stomach, but most, or all, of the cases recorded by them are imperfectly described, and were probably due to disease in every instance where the contraction was well marked; in most, however, it seems to have been only of a slight degree.

Dr. Stoker exhibited a cast of the viscus, which Dr. Barker had made for the Museum of the College of Surgeons, and several full-size drawings, showing the disposition of the muscular coats and the twisted appearance of the constriction.

Dr. E. Hamilton communicated to the Society the following case of

FRACTURE OF THE SPINE.

M——, aged eighteen, a strongly-built muscular man, was admitted to Steevens' Hospital, January 9th, suffering from the effects of an injury of the neck. His lower limbs were in a state of complete paralysis, both as regards voluntary and reflex movements; there was also anæsthesia extending to the level of an inch above the nipple; the respiration was purely abdominal, there being no action of intercostal muscles, except a very indistinct movement in the first space. He had voluntary power over the head, neck, and upper extremities, and complained of most acute pain in the shoulders and arms; the skin was cold and clammy, the pulse being slow—only 40 in the minute—with a peculiarly prolonged beat; his mental faculties were perfectly unclouded; there was no alteration of voice or defect in deglutition; he complained of great soreness in the neck, and manifested pain on pressure about the middle of its posterior aspect, but enjoyed complete power of moving the head. He stated that the night before he was at a wake, and playing leap-frog with some of his companions, he stooped down in the usual position, when a heavy man, instead of jumping clear over, leaped on him with his legs astride his neck. He distinctly felt a sudden pain, and a sensation as if something had given way, and he fell to the ground. He was able to raise himself and to walk to an adjoining room; he then became powerless, and was conveyed to hospital. The accident was pronounced to be a fracture of the spine, about the fifth cervical vertebræ. He was placed comfortably in bed, the head being supported, but it was with difficulty it was retained in its place, as he was restless, and constantly entreated of his attendants to change his position and turn him side to side. In the course of the night the water had to be drawn off, but unfortunately its reaction was not tested. I saw him next morning in consultation with Mr. Colles; he was still perfectly conscious, but there was no return of motor power. The temperature of the surface had undergone a remarkable change; it was taken by Dr. Grimshaw, and registered 106. The anæsthesia extended to an inch or so higher. The pulse was now 120. The abdomen was tympanitic; the face congested; he was still restless; the head was somewhat twisted; there was slight priapism; no difficulty in swallowing. The question of operation was discussed, but the hopes of any benefit to be derived from it in this case were so faint it was not considered expedient to resort to it; in fact, he seemed to be rapidly approaching dissolution. He died at 7 o'clock that evening, having survived the accident about thirty-six hours.

Mr. Hamilton continued to say that the *post-mortem* appearances were in every respect peculiar. The first thing which struck their attention was the intense degree of *post-mortem* livor which was present. There was not merely the usual blue-coloured appearance, especially on the posterior surface of the body, but it was covered with numerous black spots resembling the appearances with which they were familiar in cases of só-called black death. On making the necessary dissections to expose the spinal column and cord, the blood was found to be of an intensely dark colour, and perfectly fluid—there was no attempt at coagulation. On examining the column, it was found that a fracture had taken place at the fourth cervical vertebræ; the body of the vertebræ had been completely fractured or broken across. At the same time they had a dislocation of its corresponding articular process on the right side, with partial dislocation corresponding on the left side. On raising up the cord, he found it had undergone at this point a considerable amount of compression, and it was stretched over a complete bridge, caused by the body of the vertebræ. There could be no doubt the cord had suffered considerable injury from pressure, the pressure taking place on its inferior aspect. The case was interesting in three points of view:—In the first place, there was the peculiarity of the accident—a man playing at leap-frog coming down with force on the neck and breaking it across. The second point of interest was the peculiar effect produced on the circulation. When first seen, the man was cold, with a clammy skin and a pulse beating only 40 in the minute. On the day afterwards the pulse rose to 120. There was also the peculiar dark fluid blood, and the appearance on the surface of the body after death. The third point of interest was the very great elevation of temperature which occurred after the accident, amounting to 106 degrees, and being inclined to rise even above that.

The CHAIRMAN observed that hitherto they had not paid as much attention generally to the registration of the phenomena of temperature in disease as the subject deserved. He was astonished to hear of the elevation of temperature which had been recorded in some of these cases, and regarded it as a new phase in diagnosis of a most important character. He hoped that in the course of the discussion they would hear some important observations as to the result of certain injuries in increasing the temperature in the lower animals as contrasted with human beings.

Dr. ROBERT McDONNELL thought the great interest of the case brought forward by Mr. Hamilton turned on the remarkable increase of temperature which had occurred. It was not a new symptom in these cases of injury of the spine, and it had been noticed to run even to a higher degree than that recorded in the present instance. It was a pity the phenomena of heat had not been hitherto better observed in such cases. Sir Benjamin Brodie, however, long ago noticed in his celebrated paper in the "Medico-Chirurgical Transactions," cases in which the temperature mounted to 111 between the scrotum and the thighs. He (Dr. McDonnell) was absent from Dublin when this case of Mr. Hamilton's occurred, or he should have endeavoured to ascertain the temperature both before and after death. During his own accident week a somewhat similar case of cervical injury occurred. He was absent, but his resident pupil had taken the temperature with great care, and found that in the axilla it mounted to 102. This case also terminated in death within thirty hours after the injury, the subject being an old man, whereas Mr. Hamilton's patient was a young one. It was obvious, from a moment's consideration, that the increase of temperature in these cases must depend on something quite different from what it did in those cases where they found the side of the head getting warm after the cervical sympathetic had been divided. When they divided the cervical sympathetic in a rabbit, the other side became warmer, but the cause of it was purely mechanical. There was paralysis of the vessels on the one side, more blood flowed into the vessels on the other, and the temperature was increased to the hand. There was no cause here that would make the ear hotter than the heart, the lungs, or the liver. Obviously they had in these cases of injury to the spinal column, where the temperature became higher than the ordinary temperature of the circulating fluid, something to be explained very different from that which took place in the cases of injury to the cervical sympathetic. He had made some observations on rabbits to ascertain what might be the cause of this phenomenon. It was well known that Bernard had ascertained, that on puncturing the fourth ventricle, the abdominal viscera became vascular; but at the same time he (Dr. McDonnell) had met with remarkable results quite the reverse in his experience. In the first place, in experimenting on rabbits, the normal temperature of the animal should be carefully ascertained. The normal temperature of a rabbit, ascertained by a thermometer passed into the rectum three or four inches, varied considerably, but it often, within the limits of health, amounted to 103 or 104. He had often found it standing at 104. The second cervical vertebræ had a ridge at the back on which you could put your finger, and by pressing the head down the spinal column could be punctured with the greatest nicety at any point desired. Immediately after this was done there was a remarkable diminution of temperature. Within half-an-hour the temperature fell considerably, and in an hour it would fall to 97, and that even when the animal was kept near a fire. The injury, although it paralysed the lower limbs, did not kill the animal; on the contrary, it would completely recover from the effects of the wound, and the observation could therefore be extended over several days. He found that the temperature rose slowly, that on the second day it was 99, on the third day 101, and on the fourth day 103, the normal temperature; but he had never, in any case of injury to the spinal cord in a rabbit, found the temperature increase above the normal standard, as in the case now before the Society. This influence which gave rise to increase of temperature in fevers, especially in traumatic fevers, had been carefully observed in recent times by German experimentalists. The experiment had been tried of injecting into the cellular tissue putrid material such as was often found in wounds, and it was found that some produced a marked elevation of temperature, while others produced a diminution of temperature. The generally received opinion now-a-days was that the increase of temperature that occurred in traumatic fever, where, in three or four days, the temperature will rise to 102, was that it was excited by absorption of these putrid materials. Some of them produced violent local inflammation and fever; others produced a great increase of fever, without much local inflammation. The pyrogene, or fever exciter, was something which excited the blood to rapid oxygenation, and gave rise to combustion, which went on with such intensity that they had the temperature running up to 106 within a few hours. There must on that theory be some material that got into the circulation, and which excited it so as to cause the increase of temperature. He confessed he should be inclined to look in the direction of the liver, rather than in the direction of the lungs, for this influence that excited the circulation. The subject was one of great interest, and had an important bearing on practice, for when better understood they might be enabled by temperature to discover the locality injured. This increase of temperature had never been observed save in cases of injury of the cervical vertebræ. The direction he should be inclined to look to for the explanation of the phenomena was not to the disturbance of the vasa motor system simply, but to the disturbance of the vasa motor in connection with the liver, and the pouring out of some of those fluids which will excite, as pyrogene does, some of the phenomena peculiar to fever.

Dr. **Grimshaw** said there were some points in this case resembling features in the disease called cerebro-spinal meningitis. He had observed the temperature for a period of forty days in cerebro-spinal meningitis, and in some cases it had risen to a considerable height. The highest temperature on record in such cases was 110. In those cases the part generally attacked was the upper part of the spinal cord, and it was during the first period of the disease that the temperature rose to its highest point; and on the occasion he observed the highest temperature, the most intense suffering was experienced, and was referred by the patient to the back of the neck; so that the locality of the cord most affected in cerebro-spinal meningitis, was the part that had been injured in Mr. Hamilton's case. The eruptions were also similar to what he had observed in cases of meningitis.

Mr. **Hamilton** said he was inclined to believe, with Dr. McDonnell, that the great increase of temperature could not be explained by vasa motor paralysis. He thought Dr. McDonnell's suggestions worth carrying out.

The Society then adjourned.

◆

DUBLIN PATHOLOGICAL SOCIETY.

(Continued from page 142.)

Dr. **Stokes** exhibited

A REMARKABLE SPECIMEN OF GENERAL HYPERTROPHY OF THE HEART,

and remarked that one of the great advantages of this Society is that it leads us to study the phenomena of the combination of diseases, and here we have a very remarkable example of combination of diseases. The symptoms having been tolerably noted during life, we have enormous muscular hypertrophy, disease of the aortic valves, chronic pericarditis, acute pericarditis, and hydro-pericardium. This heart was taken from a young man twenty-five years of age, and his history is remarkable. It seems to be one of those cases in which disease becomes, as it were, a second nature, for this boy had been the subject of rheumatic fever for the best part of his life—that is to say, not that he had been always labouring under rheumatism, but that scarcely a year passed without his having an attack of rheumatic arthritis. Doubtless in some of these attacks he suffered from pericarditis; we have tolerable evidence that the heart was attacked some years ago, for then, for the first time, he complained of cardiac symptoms; but it often happens, in cases of chronic arthritis, that the cardiac symptoms are latent, and were it not for physical diagnosis that disease might be overlooked, and very often is overlooked. This boy was admitted into hospital with the ordinary symptoms of permanent patency of the aortic valves in the most exaggerated form. It was a model case of the disease so well described by Sir Dominick Corrigan, in which we have the phenomena of a laboured and violent action of the heart, visible pulsation of the arteries, the collapsing pulse and the double sound at the base of the heart, the murmur of exodus, and the murmur of regurgitation. It was obvious, also, in this case, that the capacity of the ventricle was greatly increased, and this conclusion we come to from observing the apparent volume of the arteries during their pulsation. This was remarkable even in the carotids. The carotids beat like the abdominal aorta, giving the idea of the same volume of vessels. It is possible this remarkable throbbing of the carotid arteries was indicative of the commencement of the pericarditis, because we know that this is one of the most interesting symptoms of pericarditis, the local increased action of the carotid arteries, as compared with the radial and femoral arteries. It was very soon after his admission that the signs of pericarditis showed themselves, and therefore I think it quite possible that this violent action of the carotid arteries may be indicative not only of the great capacity of the vessels, but of the commencement of pericarditis. The heart weighed, along with the pericardium, four pounds and two ounces, and I believe this is the largest heart that has ever been exhibited at the Pathological Society. Dr. Law showed a heart some years ago that weighed thirty-eight ounces; this weighed four pounds two ounces, and it is the true "cœur du bœuf," the ox-heart of the French. This boy may be said to have been the subject of rheumatic fever most of his life, and doubtless had many attacks of pericarditis. It can, therefore, be readily understood how it was that this enormous condition, this irritative condition of the heart, was developed, for every structure in the heart was hypertrophied. We often see, when we have mere aortic valve disease, hypertrophy and dilatation confined to the arterial side of the heart, but here the right side is equally hypertrophied with the left. The parietes of the right ventricle are of great thickness, and the right auricle is also prodigiously hypertrophied.

The walls of the left ventricle are more than one and-a-half inches in thickness, the muscular structure being very firm and florid.

There are marks of very chronic pericardial inflammation in one place, a cartilaginous deposit of great thickness, and above it the thickened pericardium. The carinæ columnæ, when taken out, were prodigiously thickened, being about the size of one's finger, and the tendinous chords also exhibited remarkable thickness. The only valvular disease that exists is that of the aortic valves. The central valve is greatly thickened, and it has a calcareous patch of considerable size in its centre; the other valves are also shrivelled—that is, the whole of the pathological anatomy of this extraordinary specimen. Except when we come to look at the pericardium itself, the whole surface of the heart is covered with lymph in great masses, very hard, in some places laid smoothly on, and in others in numerous tuberosities. On the face of the external layer it is an exaggerated representation of the ox tongue. It can easily be imagined that there must have been very violent friction experienced by this heart when the pericardium was in this condition.

There are one or two curious matters connected with this case which are worthy of record; the phenomena of pericarditis are very obvious. They were so obvious that they obscured the valvular murmurs. It was with difficulty we could hear them, owing to the ear being occupied by the tremulous rasping sound of the heart. But I want particularly to notice the phenomena of the disappearance of both murmurs immediately before death. In cases of permanent patency of the aortic valves, it commonly happens, as the patient approaches death and the heart gets weaker, the first sound of exodus disappears; but I have never known any instance where before death the second, or regurgitant sound disappeared. It always remained, though diminished in intensity; but in this case both sounds disappeared. In this case we have, as it were, a backward process in the physical phenomena. In the first stage we have the murmur of exodus, then we have the murmur of regurgitation, then both these sounds become distinct, with a throbbing pulse, a visible pulsation, and all the other symptoms; but as death approaches the phenomena take a reverse course—the throbbing pulsation ceases, the visible pulsation ceases, the double murmur disappears, and, so far as external observation, all the physical signs that were so apparent in this form of the disease subside before death, save and except the regurgitant sound. But in this case the regurgitant sound also disappeared, and the patient before death had no valvular murmur. This is to be attributed to the increasing weakness of the heart before death; but the disappearance of the regurgitant murmur can only be explained by assuming that the resiliancy of the arteries diminishes as well as the contractile power of the muscles. I have another observation to make: this young man was the son of a farmer, and was employed as a ploughman on the farm up to within one year before his death. He was a young man of considerable intelligence, and he said that he always felt better after a day's ploughing. This fact makes us review some of our practical rules as to the management of cases of heart disease. I mean particularly those where the patient is restrained from exercise.

I believe there is a case in which active exercise in organic heart disease will prolong life, or, to put it in other words, that particularly in this form of disease, whatever tends to promote the vital contractility of the heart tends to prolong life. One of the first cases of heart disease I ever saw in my practice was that of a young lad, fourteen years of age, who was attacked with pericarditis. The mother took the care of the boy into her own hands. In about six months afterwards she commenced the following system: she took him to the Phœnix Park, made him hold on by the handrail of the car and run after the trotting horse round the whole of the fifteen acres, and this was his exercise for years. He was always better after this, and when he grew up he pursued the same plan. Whenever he felt cardiac distress he mounted his horse and galloped round the Phœnix Park, and always with the result of the cessation of the distress. So also a gentleman, who was a fellow of one of our collegiate institutions. He had permanent patency of the aortic valves for years. His only method of obtaining relief was to play a violent game of cricket, and whenever he drove his pulse up to 160 he was perfectly free from all symptoms of the disease—no pain—no distress—and passed the evening in apparently perfect health.

JANUARY 30, 1869.

Dr. B. F. McDowell exhibited

THE HEART, LIVER, AND KIDNEYS OF A PATIENT,

which he believed to possess very considerable interest, showing as they did the remarkable changes which may take place in the different organs of the body under the influence of severe syphilitic infection. The patient was admitted under the care of his late colleague (Dr. Byrne) about four years ago. She was eighteen years of age, and was then a strong healthy-looking girl. She suffered at that time from an "infecting" sore, which was followed by an abundant papular eruption and intense constitutional disturbance. She had two or three minor evolutions of the poison subsequently in the form of sore throat, &c. She now lapsed into a very debilitated state, her pulse was weak and small, she was very much reduced, and assumed that peculiar look which is characteristic of profound syphilitic taint. The liver became very much enlarged, and painful on pressure. She complained of a dragging weight in her right side, and constant nausea. Under treatment she rallied, and left the hospital for the South Dublin Union. Some months ago she returned in a very wretched condition. The liver gave signs of enormous enlargement. She suffered from constant vomiting—her stomach obstinately refusing all food. She had frequent diarrhœa. She suffered from dyspnœa and palpitation. She gradually sank, and died about ten days ago.

Autopsy fourteen hours after death.—The body was very much emaciated. A large hole was visible on the right tibia. A "chronic syphilitic sore," about the size of a shilling, occupied the anterior wall of the vagina. The pericardium contained about two ounces of clear serum. Several small yellow streaks were visible on its inner surface, resembling those seen upon a syphilitic placenta, and I believe of syphilitic origin. The heart was very much atrophied, weighing only 4¾ oz. Several small syphilitic deposits might be seen upon its surface, particularly over the left ventricle. The white spot of Baillie, it will be observed, is considerably enlarged, and may almost be removed as a distinct membrane. Passing to the liver we find it to be enormously enlarged, it weighs eight pounds and a quarter, and appeared when I opened the abdomen to occupy almost its entire cavity. It is very solid looking, and wants that flaccidity which is to be observed in a healthy organ. I believe it to be an example of the acute syphilitic interstitial hyperplasia of Frerichs—it answers abundantly Virchow's test for albuminoid degeneration, as my friend, Dr. Thomas Evylin Little, has demonstrated. The kidneys were also much enlarged, averaging in weight over nine ounces. A vast number of syphilitic deposits might be observed on their surface, and their capsule was easily removable. When under my treatment the patient's urine was highly albuminous. Altogether, I consider the case one of great interest.

CYSTIC-SARCOMATOUS TUMOUR.

Dr. Fleming exhibited a tumour, which had been removed that day by Mr. Colles in Steeven's Hospital. The subject of it was a woman, aged forty years; she was married, was a mother of many children, and enjoyed excellent health. About ten years back, she accidentally perceived a small tumour, somewhat of the size of an ordinary hazel nut; it was moveable under the skin, and was situated in the right lumbar region. During seven years or so, the tumour slowly and gradually increased in size, but within the last three or four years it showed a disposition to enlarge with much greater rapidity. Under these circumstances, she presented herself at the hospital for advice; she did not complain of any uneasiness in the tumour, nor did it occasion any inconvenience in her several movements. It was very prominent, was smooth on its surface, and resting on the two last corresponding ribs, reached to the crest of the ileum. In its vertical diameter it measured between seven and eight inches, and in its transverse, somewhat less. The spinal column lay about an inch or so from the right line of the tumour. The superincumbent skin was perfectly natural, and had no intimate adhesion to the tumour, neither were any large vessels visible. Its consistence was very solid, with the exception of a limited portion, where from its great tension there was a deceptive sensation of fluctuation. Freely moveable in a lateral direction, it was less so in the vertical, and specially so over the ribs, where there was a hardness almost amounting to that of a bony hardness. The removal of the tumour was decided upon, and effected with ease and rapidity; in fact, by a free division of the integuments down to the tumour, it was as quickly enucleated as a fatty tumour, or as an encysted scalp tumour. It lay in a deep vascular bed superficial to the muscles underneath, and was found to be in weight little less than a pound. The appearance of its section resembled closely that presented in an ordinary fibro-cystic tumour of the female breast, exhibiting its several grades of development—viz., the single or the "unilocular cyst," the "compound cyst," and the final "cystic sarcoma," from the development of the fibrinous intracystic material. It constituted, as described by Sir Astley Cooper, the variety of hydatid tumour, and by Sir Benjamin Brodie the serocystic. That this special class of tumour should occur with such characteristic features in a situation such as in the present instance, must render somewhat questionable its original formation by dilatation of duct tubes.

Dr. Lyons said the specimen he had to exhibit was taken from the body of a young man, twenty-six years of age, admitted to the Hardwicke Hospital on the 17th November last, labouring under scarlatina. The history of the case was as follows:—He was a gardener in the south of Ireland, and travelled up to Dublin on the 15th November in company with a number of soldiers' wives and children, whom he heard talking about scarlatina, and this was the only occasion on which he was at any time to his knowledge exposed to the possibility of the contagion of scarlatina. His case was one of ordinary scarlatina, and he was convalescing very fairly from the disease when it was noticed that the glands in the neck began to swell. They swelled rapidly, and Dr. Lyons was under the impression that they were going to suppurate very freely. He was suitably treated, striped, and poulticed, when to his (Dr. Lyons') surprise, he found one day that a large mass of the gland which occupied the left side of the neck had quite suddenly receded. This was attended by a simultaneous development of acute pneumonia in the apex of the left lung, which ran a very rapid course, and under the influence of treatment he seemed to be convalescing from the pneumonia, when several glands on the right side of the neck became enormously enlarged, and after poulticing them for ten days he was enabled to evacuate a good deal of matter in that situation. The apex of the lung was in the third stage of pneumonia, and now he seemed to get into a sort of passive condition, the lung making no progress either towards recovery or in any other direction. He fell into a chronic pyemic condition, and depots of purulent matter formed in five or six different situations. In the small of the back two collections of matter suddenly appeared, which were evacuated, and then one appeared in front of the left thigh. A chronic pyemic condition was now obvious in the case, and he seemed not to be making any way. He continued in hospital for several weeks with comparatively little change, his strength being supported by a liberal allowance of wine, food, and tonic medicines; his pulse was exceedingly weak, and he now had night sweats. About a fortnight before his death he complained of a considerable amount of acute pain low down on the left side. It was now evident that pleuritis was superadded to the other conditions presented, and at the same time the original disease appeared to undergo some extension in the lung, and to travel downwards, but it was not until about five days prior to his death that the most remarkable symptoms of all in the case became developed. Suddenly, one morning while he (Dr. Lyons) was inquiring how he had passed the night, he began to cough, and he at once noticed the characteristic odour of gangrene in his breath. He coughed up quantities of an exceedingly foul fœtid matter of a dark greenish hue, and it was obvious that there was an enormous quantity of this in the cavity of the chest occupying the lower two-thirds of the chest, and accumulated to such a degree as to thrust the heart to the right side, and produce a very remarkable amount of dextrocardia. He daily spat up large quantities of this fluid ; it was extraordinary what a quantity he would pour out at night into the spitting vessel. He sank quite suddenly. They found on making a *post-mortem* examination, the upper third of the left lung in the third stage of pneumonia, and from that down the lower two-thirds of this organ, were converted into a deliquescent putrilaginous foul-smelling mass. So intimate was the adhesion between the pleural membrane and the surface of the lung, that it was found impossible to detach it from the ribs. A line which could be seen distinctly showed the line of separation between the still healthy lung and the diseased part. It was a sort of line of demarcation which seemed to be formed between the good portion of the lung and that which was broken down into the deliquescent mass, and the odour of which was intolerable. It would seem from looking back upon the case, as if the destruction of the lung tissue had been going on for some considerable time, and that a large quantity of the lung structure had broken down into this deliquescent state, but that this was for a time cut off by a conservative inflammatory operation from the upper part of the organ, and had no access to the external air, and the muco-purulent expectoration which he had was therefore devoid of a fœtid character. Then, suddenly under some violent access of coughing, an opening egress was effected through a bronchial tube, and he then spat up this foul-smelling fluid. It was worthy of note in this case that the condition of consolidation of the lung coincided with the sudden subsidence of the glandular swelling in the neck. They seemed to be related as cause and effect. It was further remarkable that the patient lived under this long and complicated process of disease for a period of seventy-three days from the time of his admission into hospital.

◆

THE INFLUENCE OF IRRITATION ON THE NERVES OF THE SKIN UPON THE TEMPERATURE OF THE LIMBS.

MM. **Brown-Sequard** and **Lombard** publish in the *Arch. de Phys. Norm. et Path.*, p. 688, the first results of some experiments instituted by them to determine the effect of irritation of the nerves of the skin upon the temperature of the limbs. They experimented upon each other. Being seated quietly in a room of steady temperature, one of them was pinched in some part of a limb a few moments after placing upon the same limb, or the opposite one, a thermo-electric pile, and the establishment of equilibrium judged of by the steadiness of the flame at the zero of the scale. Suppose the pile was placed on the left forearm ; now, pinching the skin somewhere on the hand, forearm, arm, shoulder, or even the neck of the opposite side, produced a diminution of temperature in the limb carrying the pile. If, on the other hand, the limb carrying the pile were pinched, no matter where, below it, at the fingers, hand, and thumb, or above it, at the forearm, arm, or shoulder, the temperature of the limb became elevated. The same results were obtained in the lower limbs. They also found that pinching the lower limb, for instance, while the pile was upon the upper limb of the opposite side, produced a diminution of temperature in the limb carrying the pile ; while, on the other hand, pinching the skin of the lower limb of the same side as the forearm carrying the pile, produced an elevation of temperature in that forearm. This elevation and depression of temperature was very little, not more than one-hundredth of a degree centigrade, the diminution being in general greater than ,the increase. The difference would have been greater had the temperature of the room in which they experimented been less elevated (19° to 21° Cent.). The maximum depression or elevation took place at the end of a minute and a half. The deviation of the flame indicating a change of temperature commenced almost immediately after the pinches. The stronger and more numerous the pinches the more marked the changes of temperature. Repetition of the experiments on the same person rendered the results, after a while, less and less pronounced. The elevation of temperature is ascribed to increase of blood in the part, the depression to a diminution ; and the phenomena of change of temperature are attributed to the effects of vascular contraction or dilatation, taking place by reflex action,

Notice to Subscribers.—Subscriptions for the year ending Dec. 31st, 1868, are now due. Subscribers resident in England will greatly oblige by forwarding the usual amount, 22s. 6d., either by cheque or P.O.O., made payable to A. A. Tindall, 20 King William street, Strand, London.

Subscriptions in Ireland to be sent to 3 Lincoln place, Dublin, and in Scotland, to Maclachlan and Stewart, South Bridge, Edinburgh.

Advance subscriptions, 21s. 8d. post free per annum, for the current year, can also be paid as above.

Registered for Transmission Abroad.

The Medical Press and Circular *is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price 5d. Stamped 6d.*

By Post to Annual Subscribers, £1 2 6
„ *If paid in advance,* 1 1 8

⁂ Post-Office Orders and Cheques to be drawn in favour of
A. A. Tindall, 20, King William-street, Strand, London,
„ 3, Lincoln-place, Dublin,

WEDNESDAY, MARCH 3, 1869.

SPECIALITIES.—THE OBSTETRICAL SOCIETY OF LONDON.

Notwithstanding all that has been said *against* specialities in medical practice, we find that there is, as in many other departments of human life, so much to be said *for* such specialities, that in all probability a considerable number of special practitioners will always exist. For our own part, we must acknowledge to having received so much enlightenment from attending the clinique of the London Ophthalmic Hospital of Moorfields, and other special cliniques, that we cannot help believing that at least ophthalmic surgery could not be so well studied by a busy general practitioner or surgeon. Is this the case, too, with the art of obstetrics? Well, we suppose it is. There seems to be such a number of diseases connected with the uterus that, without special attention to them, the subject appears in danger of being rather carelessly handled. And, if this hypothesis be granted, the formation of an Obstetrical Society must be considered as one of the best means to attain to the knowledge of the accidents of parturition, and to clear up the difficult points in the obscure pathology of female generative diseases. Not that we do not a little regret that such societies do not exist rather in the form of committees of the Medico-Chirurgical or other leading societies, instead of being isolated from the main body of medical practice. In our humble idea, there ought to exist a committee of the Medico-Chirurgical Society of London, composed for the most part of those who occupy themselves most with ophthalmic questions, another committee for those most interested in obstetrical inquiries, and perhaps another for those interested in laryngoscopy, and we should even suggest one to investigate the genito-urinary organs of our own sex. Above all, however, we do think that a committee for therapeutical inquiries ought as soon as possible to be instituted, when all questions of treatment, even the most heterodox or absurd, might be combated and freely discussed. Lastly, a committee on hygiene is much wanted. Such committees, sitting on different days, would be far better than separate societies, which waste the funds of the medical men, by no means a rich body of men, and conduce to isolation and mere special views. We cannot, above all, understand why there is no ophthalmic committee.

In hopes that our afflicted Faculty of Medicine may, ere long, get over these struggles towards better times and a more perfect unity, we welcome the existence and labours of the Obstetrical Society of London. It has already done enormous service to the cause of science. The debates inaugurated by Dr. Tilt, by Dr. Barnes, by Dr. Tanner, and other able men, have saved the female sex from many of the rash operative proceedings which required only to be fairly spoken of to be thrown aside by the majority of able practitioners. Theories such as the ulceration of the neck of the womb have been reduced to their just dimensions by the papers of Tyler Smith, and, if truth be an accordance of our ideas with the facts in nature, the Obstetrical Society has done much to reveal the truth regarding the nature of female diseases. Among the most able among the members of this useful society is Dr. Graily Hewitt, and it is with very great pleasure that we find that the society has done him the signal honour of selecting him as its president for 1869. We have no hesitation in saying that his work on the diseases of women is by far the most comprehensive and able work on this obscure and difficult subject which it has been our lot to read. And, in saying this, we have regard both to the special knowledge shown by the author of the subject-matter on which he treats, and also to the general enlightened views upon drug therapeutics generally entertained by him. With the exception that he seems more enamoured of large doses of alcohol, than the modesty of our opinions permits us to sanction, his treatment by means of drugs leaves us little to desire.

Opinions move rapidly in our day, and thus we are not at all surprised to find the president of the Obstetrical Society in favour of educating ladies to become skilled midwives. He truly observes, that midwifery, although in most cases there is no difficulty to overcome, in some cases requires all the skill and all the resources of the most accomplished surgeon. Hence he expresses his belief that "the great emergencies of obstetric practice can never be adequately met by anything short of masculine intelligence." Our lady friends will thus perceive that Dr. Hewitt considers their intellect to be inferior to that of our sex, and in this he has doubtless the assent of the great mass of mankind. We are almost rash enough to believe this to be partly true, although we should like to hear the opinion of Mrs. Somerville and Miss H. Martineau on that point. Dr. Hewitt thus thinks that the employment of midwives, as he calls them (not entertaining evidently the idea of such an innovation taking place soon, in which we believe him to be in error, in this country, as the introduction of female M.D.'s), must probably continue to be necessary "to supplement the work of medical men." But, notwithstanding this, he points out the disastrous effects often resulting from the employment of uneducated midwives. We are quite disposed to agree almost entirely with Dr. Hewitt in these liberal and enlightened remarks. Even, however, granting that women of the stamp of Madame Boivin, M.D., and the famed La Chapelle, of Paris, would require to call in the assistance of surgeons in operative cases, which we hardly think would very often occur, we must remember that there is no doubt that the ordinary run of gentlemen in general practice in London not unfrequently do the very same thing, and hence, this reason seems quite inadequate for keeping out educated women from such a lucrative employment as that of obstetric practice. Events succeed rapidly now-a-days, and the laying of the Atlantic Cable was, we imagine, a far more startling fact than the invasion of a part of medical practice by our sister sex is likely to prove to be. For our own part, we believe that social schemes are by no means all worked out as yet, and that metaphysics and theology have had too much to say in forbidding new combinations and experiments in human society. At any rate, we are not by any means arrived at that state of freedom from misery and disease which would entitle us to fear all change. The introduction of educated women into the obstetric department of medicine is, in our opinion, one of those changes which must be looked upon in the light of progress, and not merely of variety. Nay more, we would not fear the result, even if that pleasant sex should become competitors with our noble one for the emoluments of the medical, the legal, or even (alas !) the theological profession. In a word, we are considerably converted to the opinions of Mr. J. S. Mill on this question.

◆

THE REPRESSION OF QUACKERY.

The great public service which has been done in the very infrequent occasions in which quack swindling has been from time to time publicly exposed, renders it a matter of earnest regret that the occasions have been so few, and that the forcible impression which for the moment had been made upon the public recollection should never attain greater importance than the temporary interest which attaches to a nine-days' wonder. Once in every two or three years one of the legion of victims is dragged into unwilling notoriety by his connexion with some pseudo-medical blackleg, and for the time the world is all agog at the unveiling of a system of wicked swindling, of the existence of which they had not even a thought. But the very nature of the confession which a prosecutor must necessarily make to establish his case would enforce silence in all but the most exceptional cases, and before the facts have had time to exercise any beneficial influence the recollection wears away, and the swindle is resumed with increased energy. The fact is that, as in many other instances, the law of the land is not suited for the peculiar circumstances of the matter. The obligation which rests on the prosecutor to tell his own tale and to incur all the risk and opprobrium is more effective in protecting the guilty party than any effort of his own could be. The law declares that the suitor shall be listened to only in his full and public confession, and the severity of the penalty is thus actually transferred from the swindler to his complaining dupe.

It would seem to us, therefore, that obscene quackery is an evil the remedy of which ought not to be thrown upon any individual, and which may be properly taken in hand by philanthropic persons. The task of absolutely stamping out the obscene quacks is no difficult one if it be met by efficient means. The cases for prosecution are innumerable, the evidence is always at hand, and of the most conclusive description, the defence has always proved to be weak and could not be otherwise, and if the *mauvaise honte* which a solitary victim feels were sunk in the action of a committee of philanthropic men, the complete extirpation of this system of swindling would inevitably follow. We shall yet hope to see an Association for the Repression of Quackery, mentally and morally strong, devoting themselves to this work; and, with the understanding that its organisation be not open to the suspicion of professional self-interest, we shall hope to be allowed to co-operate in the movement.

◆

"PREVENTION BETTER THAN CURE."

It has at last been discovered that 72 per cent. of the paupers in the United Kingdom are reduced to pauperism by sickness, and that disease is the most expensive luxury the State can indulge in, not only by reason of the loss of labour, but because it makes paupers, who are the drones in the hive, living on the produce of the workers. Yet, as the London *Daily News* remarks, the Poor-law Medical Service is treated by Boards of Guardians *as a kind of luxurious or extravagant appendage of their administration*, and is kept *as cheap and as inefficient as possible*. The smallest item in the expenditure of the poor rate is that for the relief of the great cause of pauperism. We spend vast sums in supporting paupers, hardly anything in keeping the people from falling into pauperism. It has been truly said that the stingiest of all stingy things is the pay of Poor-law doctors. Yet there is an equally homely and familiar experience which every one goes through that might teach us not to believe that every thing which is cheap is economical. It has also been asserted that the direct consequence of the underpayment of the Poor-law Medical Service is inefficient attendance on the illnesses of the poor; that this neglect leads to a most serious and unnecessary increase of invalids and ultimately of paupers; in short, that starving the doctor means swelling the poor-rates. The low estimate at which the value of medical services is held by Boards of Guardians arises in great measure from the indiscriminate and vast amount of gratuitous medical assistance that is yearly given by the profession. This appears at last to have reached its culminating point in London, where it has been computed that 1,800,000, or about four-sevenths of the population, received gratuitous attendance from medical institutions in the course of a single year. No wonder that medical and surgical assistance that may be had to this extent for the mere asking for should not be highly prized. Many of these people, no doubt, were able to pay, more or less, for the value they received, and would have done so if it had been necessary; there was, therefore, a diversion from the medical profession of so much wealth which was clearly its due. The interest of this subject to the public lies in the fact that the unintelligent distribution of funds for the relief of sickness is constantly tending to the increase of pauperism. The interest to members of the profession is more simple: it concerns their actual existence upon the face of the earth. A contemporary, treating of this subject, says that it has "a strong and growing conviction which may be thus expressed: Very poor persons must receive gratuitous assistance in time of sickness, the State providing it, and the medical men who furnish it being adequately paid. Persons in work, but of very moderate means, must keep up an insurance against sickness by which, in time of need, good and properly remunerated medical assistance would be forthcoming; and the medical profession must cease to squander their energies and lives in ministering gratuitously as they now do."

◆

SCOTLAND.

EDINBURGH.

THE INFIRMARY SITE.

An excellent letter addressed to the contributors of the Royal Infirmary by Professor Syme appears in the *Scotsman* of the 22nd ult. We have watched the controversy on this subject while passing through its several phases, and we own that to us at this distance the weight of argument seems to incline to the side taken by the learned Professor. His statements, we suppose, cannot be denied, and his conclusions must therefore be equally well founded. We can only quote the more prominent portions of his letter. After showing that nothing had been done which could lead to a decision, he observes—

"There are two great questions to be considered—1st, Whether the new hospital should be entirely medical, or contain surgical as well as medical wards? 2nd, Where it should be built?

"With regard to the first of these questions, seven out of the eight surgeons employed in the service of the hospital have expressed their opinion that it is defective in salubrity, and also in the arrangements at present deemed requisite for such establishments. It is also maintained that the construction of a new hospital with all modern improvements in immediate proximity to the old one would bring out all its defects in still more glaring relief.

"As to the second question, the managers originally proposed that additional space should be obtained to the extent of one acre for building a merely Medical Hospital by the purchase and removal of houses valued at from £60,000 to £70,000, and have scheduled a bill to this effect, which is now or was lately before Parliament. But as this plan, with the other necessary expenses attending it, would absorb the whole amount that has been subscribed for building the new hospital, the General Court of Managers has advised that the application for an Act should be withdrawn, and the Court of Contributors has approved of this resolution."

Referring to the four other plans which have been proposed he showed serious objections which may be brought against them, and then went on to say:—

"The ground of Watson's Hospital is nine acres in extent, and must be regarded as fully sufficient for the purpose, since the existing site extends to only five acres, and if enlarged by the space scheduled in the managers' bill would not be more than six acres—while Mr. Bryce, in one of his plans, speaks of seven acres as being abundantly ample. It is a south-west exposure, instead of one to the north-east like St. John's Hill. It is permanently free and open on all sides, instead of being hemmed in by the constantly increasing density of a crowded population. It is considerably nearer the College than St. John's Hill, and affords ready access to patients from every part of the town. It is uniformly even and gently sloping, instead of being precipitous and irregular like St. John's Hill, and the present sites. It has long been remarkable for the healthiness of its situation. It admits of the most perfect drainage at an expense of £300. It may be acquired for

£43,000, from which, if £17,000 (the estimated value of the present Infirmary buildings) be deducted, £26,000 will remain as price of the site. Lastly, a new hospital may be built here without disturbing the old one, injuring the Medical School, or depriving the patients of relief."

He then proved that the defects attributed to the grounds of George Watson's Hospital were simply imaginary, and concluded by warning the contributors that "unless the question were fairly considered, there was great risk of important interests being sacrificed to the gratification of personal vanity—the pecuniary advantage of greedy officials, and the bigoted obstinacy of narrow minds."

ASYLUM FOR THE INSANE.

DR. SKAE read his report at the annual meeting of the Corporation of this Institution. A variety of interesting and important particulars were presented to the attention of the meeting. The number of inmates was 720 on the 31st December last. During the year 121 had recovered, being in the ratio of 43·4 per cent. to the admissions, while from the commencement the ratio was 38·5 per cent. This is considerably less than the percentage of all the large asylums in England. The mortality has been lower than it was for many years preceding the improvement of the dietary. Numbers had been refused admission for want of room, among whom were patients of the higher class, whose friends would have paid from £80 to £400 per annum for their board. Designs were obtained for the extension of the department for these higher class patients and for other improvements, but these buildings were for the present delayed. The funds of the Institution are in a very satisfactory condition.

WATER SUPPLY.

THE different Municipal Wards of the City of Edinburgh have held their meetings, and have all voted their approval of the Council taking over the works of the Water Company, and carrying out the St. Mary Loch Scheme. Some difference of opinion existed at one meeting as to who could claim the majority. The Lord Provost declared the motion carried, but the vote was a very close one. This and the question of the Infirmary site seems likely to divide opinion for some time to come.

ST. ANDREW'S.

DEATH OF PROVOST MONCRIEFF.

THE sad intelligence, says the *Scotsman*, of the death of Lieutenant-General George Moncrieff, Provost of St. Andrew's, reached the city on Tuesday morning, and was announced to the citizens by the tolling of the town-church bell. The sad event took place on Monday evening, at the Alma Hotel, Princes' street, Edinburgh, where the General was taken seriously ill about three weeks ago. Lieutenant-General Moncrieff was appointed Provost of St. Andrew's in November 1867, and continued to discharge the duties of that office with marked ability, acceptance, and satisfaction, up to the time he was taken ill. His loss will be deeply felt by all classes of the community, by whom he was deeply beloved, and is now sincerely sorrowed for.

CUPAR.

THE LUNACY BOARD.

A MEETING of the Fife and Kinross District Board was held on the 24th ult., at which Sir James Coxe gave in his report in reference to the proposal to add additional accommodation for sixty patients. He said it might be doubted whether this additional accommodation would prove sufficient for the wants of the district for more than a very limited number of years, unless efficient means were adopted to prevent the transmission of cases unnecessarily, and to facilitate the removal of those for which asylum treatment was no longer required. Application on this point was made to the General Board, who said it could best be done by the Parochial Boards sending their own medical officer to examine those they wished removed and to select such as appeared incapable of receiving further benefit and might be safely removed elsewhere. The Board agreed to appoint an assistant physician to the Asylum.

FALKIRK.

PAROCHIAL BOARD.

THE Committee report the prevalence of fever amongst the poor in the parish, and state that the accommodation in the hospital having been found to be inadequate, they have contracted for an extension of the same. The Stirling District Asylum having been opened, the lunatics confined in the poorhouse have been removed to the new asylum, where the cost per annum for each will be £25, as against £16 in the poorhouse. The Committee regret to report that in this parish, as well as throughout the whole country, pauperism is on the increase. It was agreed to add £10, which had fallen back into the hands of the Board, to the salary of the present medical officer, Dr. Espie, who had all along very ably and efficiently discharged his duties.

◆

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

PARIS, FEBRUARY, 1868.

JURISPRUDENCE OF INFANTICIDE AND DELIVERY.

THE difficulty that sometimes surrounds charges of infanticide, and the skill required to pronounce on the question of recent delivery, have lately been illustrated here, in a painful case that has attracted a good deal of attention.

A young woman named Bernard was tried and condemned last November to six months' imprisonment, on a charge of concealing the birth of a child. The prosecution alleged that in October, having given birth to a child, she threw it into a pigstye, where it was devoured by the pigs. No evidence was tendered to show whether the alleged child was born alive; but the young woman confessed as much as I have stated. A surgeon and a midwife who examined her on her arrest, testified that they found traces of recent delivery. Sentence being duly passed the girl went to prison, where, a month later, she gave birth to a fully developed child. It would thus appear that the conviction had been a great judicial blunder. The time, however, for an appeal had gone by, and it seemed not unlikely the poor girl would have to remain in prison for the full term. Scandalised at the facts, the public prosecutor took measures to secure a re-hearing in some form of appeal. The girl now stated to the Court that her mother and the midwife had persuaded her to make a false confession, as they declared that the punishment in that case would only be light, whereas persistence in denial would go against her, and with such medical evidence would lead to her being condemned for a long term of years to the *travaux forcés*. The doctrine of superfœtation, which has caused so much discussion among jurists, was imported into the new trial as a mode of accounting for the medical evidence of the former one. Like many of your contemporaries, I rejoice that this doctrine was rejected by the Court, and that the sentence has been reversed; for few will deny the more probable explanation to be a blunder on the part of the medical witnesses. Some people think that the French have carried the use of experts to perfection. This trial makes one feel these witnesses may sometimes be too expert. There is reason to fear that the experts as a body are too pliant, and too often act as witnesses for the prosecution. If this be so, the English plan of admitting a similar skilled evidence on both sides may not after all be worse than the French.

THE POST-OFFICE DELINQUENCIES.

Speaking of Vienna reminds me that the French post-officetreats Austria with peculiar injustice. Letters are almost always delayed, while nearly all the Austrian newspapers are absolutely confiscated on the frontier. My correspondents have sent me a considerable number of papers lately, but not one has reached its destination, and I am told that this is universally so. It is no great loss to me, to be sure, for I have the greatest difficulty in reading German ; but there are not a few who revolt against this detestable practice, and surely they might let medical journals pass without much fear. Let me add that again last week your paper took three days to reach me ; that your contemporaries of Saturday reached here only on Wednesday ; and that several copies of the *Times* (which I have posted to me daily), published since I last alluded to this subject, have never come to hand at all. Paris, with all its advantages as a residence, has some sad vexations.

HOMŒOPATHY.

I gave you some account a little while ago of the French homœopaths. A pamphlet has just been put into my hands by Dr. Teste, which has made a little talk. It is published by Baillière, and is in the form of a letter to Dr. Maguet, of Dampierre-sur-Sallon. It is only, in fact, the dedication of a new edition of Teste's *Comment on devient Homœopath ;* and it opens with the old song, "Nihil Contemnere," and then proceeds to relate a set of cases of poisoning by belladonna, on which an appeal is grounded to subscribe to the dogma, *similia similibus*, with what reason let your readers judge. It happened in a nunnery, under the care of Teste, that a decoction of belladonna was made as a drink instead of one of wild chicory, and that fourteen of the nuns partook of the beverage. The usual symptoms ensued, except in two of the girls, who were ill at the time, and were cured instead of poisoned by the drink. Dr. Teste saw all nine hours after the accident. Meantime, strong coffee had been recommended by a pharmacien, and given to seven of them. The others, in the confusion, had been neglected, and so taken nothing. Dr. Teste ordered those who had taken the coffee to continue it. To the others he prescribed infinitesimal doses of opium. The next day, according to the assertion, the results were marvellous. Those treated by coffee remained in a most dangerous condition and quite senseless ; while those who had only taken the infinitesimal quantity of opium had recovered their mental powers before the middle of the night, after which they had had a refreshing sleep, from which they awoke convalescent. All this, of course, because one soporific is homœopathic to another, argues Dr. Teste. He tells us, however, absolutely nothing as to the varying quantities of the drink that may have been taken, and some other points equally important to the comparison. He merely adds that he tried experiments on some chickens ; but these were not injured by the belladonna, so that he could learn nothing thereby.

Nothing fresh is stated in the pamphlet, but many old statements as to the virtues of certain globules are repeated. One thing is, however, worthy of remark. The author says, make a trial—all he asks is a fair therapeutical experiment—pending which the experimenter should not discuss homœopathy. He says "cure first ;" afterwards it is time enough to say *how* you have cured, if it seem proper to say.

Herein lies the secret of much of the opposition that has been excited, and of much of the quackery that has been practised. Men proclaim themselves followers of some pathy and ignore everything else. They laugh at the history of the healing art, and then wonder they are pooh-poohed as quacks. To dub oneself —path is to call in the public to reason on things they know nothing about, is, in fact, to appeal to the weakness of human nature in order to gain patients.

Notes on Current Topics.

Vaccinophobia.

The vaccino-maniacs have been brought to their senses and to good manners by a recent prosecution in Sheffield. The defendant was Thomas Orton, a master tailor, and secretary of an anti-compulsory vaccination committee, and he was summoned for the publication of an anti-vaccination handbill, in which libellous statements were made about Alderman Saunders, late chairman of the Sheffield Board of Guardians, on account of his attempts to enforce the Vaccination Act, and with a view to prejudice him at the next election. The handbill made out vaccination to be the mark of the beast spoken of in Revelations ; and described Alderman Saunders as a wholesale murderer, urging on, like another Herod, the slaughter of the innocents. The bench held the handbill to be a libel, and, publication being proved, they committed the defendant to the assizes for trial. The analogy between the mental calibre of vaccino-maniacs and spiritualists appears so close that we should suggest that the aggregate idiotcy of both organisations might be justly amalgamated. Mr. Home would make a creditable Financial Secretary, and Sir J. Jervoise might enjoy the double honour of being Parliamentary advocate of free-trade in small-pox and spiritual community of goods.

Prince Leopold's Health.

Her Majesty the Queen has the entire sympathy of the medical profession, who can alone thoroughly appreciate the urgency of the circumstances in the affliction which has compelled her to forego the reception of her Parliament at Buckingham Palace. With great regret, and much apprehension for the future, we have learned that Prince Leopold is a sufferer from the hæmorrhagic tendency in a very marked form, and that now for the second time he has experienced internal effusion of blood so serious in degree that great fears were felt as to the Prince's recovery. On the first appearance of the hæmorrhage Dr. Hoffmeister was called in, and had charge of the Prince until Sir William Jenner's arrival at Osborne next morning. Fortunately the treatment was remarkably effectual, and the bleeding was summarily checked ; and the attack was on the whole much less prolonged and less dangerous than on the last occasion. Our readers will, of course, estimate for themselves the chances of the hæmorrhagic tendency being successfully combated in future years, and will not fail to experience the gloomy anticipations which the existence of the diathesis in early youth necessarily suggests.

Naval Retrenchment.

The Naval Hospital Commission, appointed by the Lords of the Admiralty, consisting of Dr. C. Murchison, Mr. T. Holmes, and Mr. Robert Ellis, completed its inquiry into the organisations of naval hospitals by a careful inspection of Haslar Hospital, terminating on Thursday last week. The results of this inquiry will shortly be submitted to the authorities, together with the recommendations suggested during its course. The hospitals visited have been the Melville Hospital at Chatham, the Royal Hospital at Plymouth, and Haslar Hospital. The organisation of the marine infirmaries at Portsmouth and Plymouth has also been carefully inquired into.

Health of Southampton.

Owing to many sanitary improvements, the health of this town has much improved during the last few months, and the death-rate, according to the quarterly return just issued by the indefatigable officer of health, Dr. MacCormac, is only 22·69 per 1,000, as compared with 26·26 per 1,000 in the previous quarter. This return cannot be considered otherwise than most satisfactory, when we consider the constant influx of seamen of all countries, from the tropics to the polar regions, into this port. The report before us alludes to some of the former pests of the town, such as the slaughter-houses, lodging-houses, &c., which are now, owing to the strict surveillance of the health officers, in a very satisfactory condition. There is, however, one great nuisance still unabated, and to which the attention of the Board is particularly drawn, and that is the nuisance caused by the inundations of sewage matter in some parts of the town. Such a state of things can only end in an outbreak of some form or other of fever, diarrhœa, diphtheria, or even cholera, and we hope the authorities will take immediate steps to remedy so dangerous an evil.

Compulsory Vaccination in San Francisco.

Small-pox has been raging in San Francisco since last July, and the Board of Health there has appointed public vaccinators who are to vaccinate all persons under a penalty of 500 dollars, or 100 days' imprisonment. They will not guarantee the purity of the lymph. Persons may be vaccinated by their own medical man.

Whenever small-pox appears in a house a policeman is stationed at the door in order to prevent anyone either entering or leaving it except the doctor and the nurse. No child will be admitted to a school unless it is vaccinated, whether it has been already vaccinated or not; and it is common to see old men and women with their arms in slings under the effects of the operation.

A Working Man's Movement for Hospital Extension.

A special committee appointed by the governing body of the Queen's Hospital has made known the fact, that the out-patient department of that institution is altogether insufficient for the large and steadily growing demands upon the charity, and it has therefore been suggested that a new out-patient and accident department may be erected with great advantage on a piece of ground immediately adjoining the Queen's Hospital, the freehold of which has been purchased by the Governors.

A number of managers, foremen, and artizans employed in several of the principal establishments in the town and district, believing that the working classes would be glad to lend a helping hand in the good work, offered to assist the hospital committe, by organizing a scheme for collecting subscriptions in the manufactories, workshops, and trade societies of the town and neighbourhood. This offer has been accepted with expressions of gratitude; and the Queen's Hospital Committee have added that they will be most happy to co-operate with the artizans in their endeavours to increase the efficiency of the hospital.

Among the objects which the promoters have in view are :—

1.—The classification of out-patients in separate waiting rooms, so that a healthy person suffering from a trifling accident, or another the subject of some harmless complaint, may not be compelled to wait in the same room with others afflicted with contagious diseases.
2.—Baths for out-patients, to lessen the risk of the public baths being used by sick persons.
3.—Carriages and stretchers of proper construction for the easy conveyance of the sick and wounded.
4.—Carriages for contagious cases, which are now conveyed in cabs and other public vehicles, to the great injury of the public health.
5.—The appropriation of the detached building now existing at the rear of the Queen's Hospital, for contagious cases.
6.—The establishment of a fund to provide working men whom accident has deprived of their limbs, with the best made artificial substitutes.
7.—The erection of a conservatory, which shall be available for convalescents at all seasons of the year.

It is proposed that the workmen in every factory and workshop hold meetings, elect representatives on the General Committee, and agree to a plan for collecting subscriptions amongst themselves. Bodies of workpeople below 200 have a right to elect one representative on the General Committee; two, when above 200.

We hail with satisfaction the action of working men in furtherance of the medical relief of their own class. They have many and great interests to subserve, and a task of reform before them worthy of their efforts, and it would be the surest guarantee for effectual public sanitary guardianship if those most interested would lend their personal and pecuniary influence in its aid.

The Hunterian Oration.

The oration this year was delivered by the President himself, Mr. Quain—a combination of offices that has not often occurred. Needless to say it was well attended, being, as usual, the surgical reunion of the year. Mr. Quain's tribute to Hunter will appear in a separate form, and will no doubt be widely read by the many who could not hear it. Here we need only remark that the orator devoted much attention to the subject that is uppermost in so many minds—education; and that this was considered, of course, with special reference to professional education. Mr. Quain ranges himself with those who would devote larger attention to modern languages, physical science, and all branches of so-called "utilitarian" study, as distinguished from the old classical system. For our own profession he advocated long training of a preliminary character, and did not believe that merely making examinations more severe would suffice. This stringency did not lead to the acquirement of solid knowledge. There can be no doubt but that the force of this argument will be increasingly felt by all who are paying attention to the present system, and we should be glad to see any plan which would secure a longer preliminary training for medical students. It is, however, extremely difficult in the present condition of the country to secure it. Still, Mr. Quain has done good service in devoting so much of his oration to the question of the year. Our columns have borne witness of our desire to do our share in promoting the great reform needed, and it is very encouraging to see a President of a Royal College thus keeping "founder's day." No better way of honouring Hunter in an oration could have been selected.

Extra Medical Expenses for Military Hospitals.

In the present retrenchment furore the following extracts from the Army Estimates for 1868-9 will be read with interest:—

NETLEY HOSPITAL.

1 Governor and Commandant, in addition to £456 5s. unattached pay	£600
1 Staff Captain and Assistant Commandant	303
Contingent allowances to do.	73
Captains of Orderlies	146
	£1,122

WOOLWICH.

1 Governor, in addition to half-pay, £200 15s.	£350
1 Captain of Orderlies	137
	£487

CHELSEA HOSPITAL.

1 Governor	£500
1 Lieutenant-Governor	400
1 Major	360
1 Adjutant	210
6 Captains of Invalids	388
1 Quartermaster	158
	£2,016

The New Nomenclature.

The work to which we have several times referred during its progress is now on sale. Our readers must be familiar with the general plan of its contents, so that we need not again repeat it. We are, however, desirous of urging that it should at once be universally employed, and of stating our opinion that even a Government pledged to economy might vote a sum towards what is in effect a national work. The London College of Physicians, in bringing out this work, has conferred a great obligation on the country, and we hope that its continued revision will be as carefully carried out as that of the London Pharmacopœia used to be. To those who have done the hard work in this case the profession will render due honour; still, ought not the country to render something more substantial?

Public Health for 1868.

We have in our hands the Returns of the Registrar-General for the past year, and the following particulars which we select from them appear to be of general interest. London, he says, is still growing greater. Its population has not been counted for seven years, but it is probably 3,126,635. The constant flow of strangers into it exceeds the outflow of its children to all the parts of the empire. The people live in 400,778 houses; the streets are irregular and often narrow, but the elevation of the houses is not so lofty as to cover the streets with unhealthy shadows. The annual value under county rate assessment exceeded 15,000,000*l.* On the whole the water supply is satisfactory, and in the summer months, according to Dr. Frankland's analysis, the waters attained an unusual degree of purity. The sewerage of London is approaching completion, and when the northern lower level sewer is finished and the branches of all the sewers are in safe communication with the houses, when the sewers are well cleansed and ventilated, and when the sewage is utilized, this system of treatment will be in full operation, and the weekly returns will test its efficacy. After correction for all disturbing elements, the mortality was found to be at the annual rate of 23·59 in every 1,000 of the population. It has been regularly decreasing in South London every five years since 1845, and in the last year it was 23 per 1,000, and is now lower than in North London. Diarrhœa was unusually fatal, 4,060 deaths in the summer, and 320 deaths by simple cholera were registered. The other fatal zymotic diseases were fever 2,483 deaths, scarlatina 2,921 deaths, whooping-cough 2,369, measles 1,989.

The late Dr. Wardrop.

The death of this veteran has severed an important link with a generation passed away. The trusted friend and surgeon of George IV., the brilliant *littérateur* and associate of the elder Wakley in the early career of the *Lancet*, the skilful surgeon who could maintain a hospital single handed as a school worthy of the visits of all foreigners who came to the metropolis, the physician who placed on record his written opinion on the case of George IV. for the perusal of Halford and Knighton, the genial gentleman full of knowledge of "the good old times," the associate of Lawrence in a professorship, and in the famous education speeches of Freemason's Tavern, —in him, indeed, the profession has lost what no one can supply. He had the materials for a history that would have been eagerly perused by all, and could have shed a flood of light on many a dark page of professional and social biography. Born in Scotland he went to the High School of Edinburgh, began the profession under his uncle Dr. A. Wardrop, passed to the Edinburgh Infirmary, and afterwards to London, where Cooper, Clive, and Abernethy continued his instruction. Then he went to Paris and Germany to finish his education, returned to Edinburgh to commence an active career in practice and literature, but eventually migrated south, taking up the position in London to which the reputation he had achieved entitled him. He was elected F.R.C.S. Edin., 1804. Graduated M.D. at St. Andrew's in 1834, and ten years later became Fellow of the London College. He was born August 14, 1782, and died on the 13th February last, in the 87th year of his age. Amongst his numerous writings may be mentioned his Life of Baillie and his work on Aneurism which appeared in 1828. He had previously contributed to the "Encyclopædia Britannica" the article on Surgery, and his pen furnished those on Aneurism and Anastomosis to "Costello's Cyclopædia." His later work on the Heart is well known to every medical reader.

Physical and Mental Culture.

Dr. Bence Jones has written an able and exhaustive letter, in which he protests against the premature over-working of human brains. He says the prize system is ruinous to boys. They leave school after undergoing its influence "repelled from all knowledge" and permanently injured in health. The arguments adduced by Dr. Jones appeal more particularly to the common-sense portion of teachers and the public. He maintains that as physical exercise judiciously applied is conducive to health, and the muscular development of the human frame; and, on the other hand, as over training—which means overstraining the tissues of the body—is a most dangerous practice; so is it with mental culture. Tutors and parents, either from the go-ahead system of the present day, from pecuniary circumstances, and other causes, seem to vie with each other in keeping the brains of youths under their care in a constant state of high pressure. The half of each twenty-four hours is considerably exceeded, if not in actual schoolroom work, in hard study at home. Little time is thus left for recreation or exercise; the brain before it is thoroughly formed is overweighted, and the mischief that often supervenes is incalculable. We would impress upon all whom it may concern that they should not fail to recognize this truism in its entirety. If "the race is to the swift the battle is also to the strong." Youths with stout frames will fight the battle of life much more successfully than those whose constitutions have been enfeebled, their health undermined, and their brains overtaxed with the cramming and grinding of the modern system of education.

The Navy Estimates for the Years 1869-70.

It appears from the Estimates that have just been furnished to Parliament that the amount to be voted for the current year towards the expenses of "Medical Establishments at home and abroad" is £54,757. The sum granted for the same purpose last year was £64,824, showing a decrease of £10,067: whilst the amount required for "Medicines and Medical Stores" is £79,300, against £78,164 for 1868, showing a further reduction of £1,136. We sincerely hope this clipping of £11,203 will not impair the efficiency of this valuable department of the public service.

Her Royal Highness Princess Christian gave birth on Friday last to a Prince. The health of the Princess and infant is satisfactory.

Prince Leopold has returned with Her Majesty to Windsor, having recovered from his recent severe indisposition.

We have heard that Mr. Adams will retire from the office of Surgeon to the London Hospital. He has discharged the office for twenty years, and, no doubt, will be appointed Consulting Surgeon.

A child was poisoned at Gravesend last week through the mistake of a chemist, who dispensed strychnine instead of powdered sugar. It appears that he had lately taken the business of another chemist, and had mistaken the word "strychnia" for "saccharum."

We hear that the Secretary for India has directed that whenever any officer of Her Majesty's Indian Medical Service shall be provided with a passage on board one of the troopships destined for that country he will be entitled to Indian pay and allowances upon landing at Bombay, or other port.

The Lords of the Privy Council have revoked the restrictions respecting quarantine which were imposed in October, 1867, whilst yellow fever was raging at St. Thomas's Island. Vessels calling at that port from the present date will not, therefore, be required to show a clean bill of health prior to disembarkation in England.

The proposed scheme of drainage by irrigation of the city of Winchester has suddenly collapsed, owing to the enormous expense the plans submitted for the consideration of the Board would entail upon the ratepayers. The city is not a large one, and to ask its inhabitants to stand the brunt of £100,000 in a doubtful experiment was a little too much to expect.

The Chancellor of the Exchequer received a deputation from the Royal College of Physicians on Thursday last. The object was to ask the Government to distribute to each registered medical practitioner a copy of the "Nomenclature of Diseases" recently issued by the College. Mr. Lowe promised to consider their request.

The weekly charge for the maintenance, lodging, clothing, and other expenses connected with the lunatics confined at the Colney-hatch County Lunatic Asylum has been reduced from 10s. 2½d. per head to 9s. 11d.; and for those at the Hanwell Lunatic Asylum from 10s. 9½d. to 10s. 2½d. per head for lunatics chargeable to the county or any parish in the county; for others the charge remains at 14s. per head per week.

A meeting was lately held, in the Town Hall at Stamford, on the subject of the local charities, particularly in reference to Browne's Hospital, the funds of which are now very large. The Inspector had viewed the hospital buildings, which afforded but miserable accommodation, and which were absolutely dangerous. Several proposals were made to the meeting, but no immediate steps were taken.

The *Architect* says that Dr. Chadwick, of Southport, has just presented to the town of Bolton, where he formerly practised, £5,000 towards the erection of modern dwellings for the poor, and an orphan asylum. Only twelve months ago Dr. Chadwick made a bequest to the town of £17,000 for the same object, so that the total amount of his gift is now £22,000.

One result, remarks Dr. Ballard, of the high atmospheric temperature of the month of January has been that the mortality in Islington has been much less than is customary in this month. The deaths registered amount to 350. Had the death-rate of January for the last ten years prevailed, the registered deaths would have amounted to 417. Dr. Ballard has frequently notified the fact that the number of deaths cannot be taken as the index of general sickness or healthiness; so in this month the sickness recorded in the public practice of the parish has been excessive. The cases on the books amount to 3,201, about 400 more than in January last year.

In the parish of St. Marylebone a parochial mortuary and *post-mortem* house has just been completed. The Sanitary Committee of the Vestry are now considering the rules and regulations for the management of the building. It is fitted internally with a commodious dissecting table, is well supplied with water, and contains everything necessary for the conducting of *post-mortem* examinations, excepting surgical instruments, which each operator will be required to provide for himself.

Dr. Letheby, the Medical Officer of Health, reported to the Commissioners of Sewers that, during the preceding week, 494 houses had been inspected, and that 43 required sanitary improvement in various particulars. Seventeen of the sanitary orders of the Commission had been executed, and 49 were in hand. Thirty-three ships had been examined, and two of them were deficient in ventilation in the forecastle. Notices had been served upon the captains, who had undertaken to amend the same.

Seventeen years ago the City Orthopædic Hospital was opened in Hatton Garden for the cure of club-foot, diseases of the spine, and contraction of the limbs. Nearly 17,000 patients have been under treatment since its opening, and some remarkable cures have been effected. The annual dinner was held at the London Tavern this day week—Baron Rothschild presiding—when the subscriptions amounted to more than £600.

Naval Hospital Commission.—This Commission, appointed by the Lords of the Admiralty, consisting of Dr. C. Murchison, Mr. T. Holmes, and Mr. Robert Ellis, completed its inquiry into the organization of naval hospitals by a careful inspection of Haslar Hospital, terminating on Thursday. The results of this inquiry will shortly be submitted to the authorities, together with the recommendations suggested during its course. The hospitals visited have been the Melville Hospital at Chatham, the Royal Hospital at Plymouth, and Haslar Hospital. The organization of the marine infirmaries at Portsmouth and Plymouth has also been inquired into.

Workmen's Contributions to Hospitals.

Mr. Spackman has called the attention of the working classes of Belfast to the fact that in Glasgow and other large towns the hospitals are nobly supported by them, and that the General Hospital in that city receives but a small and unsteady support from the operatives, being last year but £115 17s. 1d. The Glasgow Hospital report shows that there the operatives contribute annually about £6,000 towards that Institution, thus affording it a steady permanent support. During the year 1867, there were 628 medical and 1,023 surgical cases admitted into the Belfast General Hospital, and nearly 3,000 extern patients attended to. This brief statement should be enough to induce all the workers in Belfast to contribute their mite, however small, and resolve to do so annually. Mr. Spackman suggests the following plan for carrying out this object:—"Let a day be appointed in each establishment as the 'Hospital collection day,' and let the workers select one or two of their chiefs to superintend the collection, and on the pay day, so fixed, let each worker give one quarter of a day's pay. For instance, those receiving 10s. per week will pay 5d., those receiving 12s. per week, 6d., and so on through all the different rates, male and female alike. These small sums collected once a year, Mr. Spackman says, 'would yield in the aggregate at least £1,000, and could scarcely be begrudged by anyone for so good an object.'" This plan appears to be very feasible, and might be adopted with advantage by other cities besides Belfast.

◆

Literature.

We may direct attention to a paper on "Tinea Decalvans," by Dr. C. Drysdale, to be found in the new number of the *Journal of Cutaneous Medicine*, so ably conducted by Mr. Erasmus Wilson, who, it will be seen, gathers into his garner the contributions not only of specialists but of a number of gentlemen whose talent or opportunity has enabled them to touch various subjects in the range of medical practices in literature. The same number contains the eighth lecture of Mr. Wilson; it is on Eczema. In the editorial commentary will be found an interesting notice of the late Dr. Helier.

The *Half-yearly Abstract of Medical Sciences* and the *Retrospect of Medicine*, conducted by Drs. Braithwaite, deserve the usual acknowledgments so often accorded to them.

The *Medico-Chirurgical Society* has issued the 51st vol. of its *Transactions*. It contains less than half the papers read in the session and cannot fail to produce much dissatisfaction. Some of the papers admitted are certainly not equal to others that have been excluded. The duty of selection is in all cases a difficult one. We should question whether much has not transpired to induce a complete change in the proceedings of all our Societies.

The *Westminster Review*, which invariably contains much to interest medical readers, has this time an important article on the adulteration of food and drugs. As it will be extensively read by the profession we need only mention here that the *Westminster* writer approves the Bill of Mr. Postgate, which we described last year in full.

Transactions of the Pathological Society, vol. xix., 1868, p. 492, comprising the Report of the Session, 1867-68.

It has always appeared to us that the name "Pathological Society" does not quite express the objects of this admirable Society, the well edited transactions of which lie before us. The name Morbid Specimen Society would better, at any rate, convey to the mind the nature of the business of the Society. And in this respect, the Pathological Society has rendered an immense service to the advancement of medical science by collecting into one focus the different observations in the *post-mortem* room made by its members. An admirable arrangement of the business of the meetings is made by classifying together the different morbid specimens of the various regions, such as of the nervous tissue, the respiratory, the circulatory and the digestive organs. The first 39 pages are devoted to a narration of cases in which the brain and spinal cord have been diseased, and to the appearance of the parts after death. The first case in the book is highly interesting and is that of embolism of the middle cerebral artery, and disease of the brain with hemiplegia from which the patient recovered, followed by death from disease of the kidneys and dropsy. The patient a man aged twenty-one, had suffered from rheumatic fever at the age of seven, and had recently in 1866, when carrying a sack of coals, become giddy and hemiplegic on the left side of the body. On removal to hospital a prolonged systolic bellows murmur was heard propagated along the vessels. He recovered from the hemiplegia, and in 1867 became an inmate of the University College Hospital under Dr. Wilson, where he died. On examination it was found that the aortic valves were almost completely destroyed, and covered with warty growths, so that the aortic orifice was much narrowed. The brain was healthy, except in the portion immediately below the sylvian fissure of the right side. Here there was a tract, with an area of three-quarters of an inch, much indurated, smooth, firm, and glistening on section, and pigmented in spots of a reddish-yellow colour. The anterior branch of the middle cerebral artery, immediately beyond its bifurcation, was completely obstructed by a firm mass of fibrous character, intimately and inseparably united with the coats of the artery.

The next case is equally important and curious. It is one of paralysis with muscular degeneration, or paralysis with apparent hypertrophy communicated by M. Duchenne. In such cases as those related by the author of this communication, there is first, it appears, a stage of paralysis, then one of hypertrophy, and, finally, one in which paralysis becomes general. The patients, although very weak, have the appearance of great muscular power, and are described as looking like "young Hercules." Cases of this kind, when, examined after death, exhibit an appearance of fatty deposits in the muscles, which at certain points cannot be distinguished by the naked eye from the subcutaneous adipose tissue. There is, however, no actual fatty degeneration of the muscles. Lipomatous atrophy is the name suggested. Mr. Lockart Clarke observed increase of the fibrous and connective tissue of the muscles.

Two very instructive instances of tumour in the pons varolii are narrated by Dr. Allbutt, of Leeds, one from a young man of eighteen years of age; the other from a girl of about nine years. In both of these cases the left conjunctiva was inflamed; in both there was paralysis of the sixth nerve; in both paralysis of the seventh nerve; in both partial deafness of the left ear; in both paralysis of the right limbs. In the boy there was no vomiting, in the girl, vomiting for many weeks; the speech was not affected in either case, nor the intellect. The optic discs and retinæ were natural. Death was caused by suffocation in the boy, and from stupor in the girl. In neither of the cases was sugar or albumen discovered in the urine. The mouth was drawn to the right in both, and the orbicularis in both paralysed. Sensation was doubtful. The temporal and buccinator muscles were not paralysed. The symptoms in such cases do not depend on the nature of the tumour, but on its situation in the brain. The tumour in the boy's brain was on the nervous tissue, that in the girl's brain was a villous growth of the pia mater. In the boy's brain the tumour involved the pons chiefly the left side, so that the organs of the left fifth and seventh nerves were included in its edge. The body of the pons on both sides is, however, largely implicated. It overhangs, but does not invade, the crura cerebri. The left side of the medulla oblongata, especially its anterior pyramid and olivary body, is enlarged, and also the same parts of the right side to a less extent. In the girl, the tumour involved the left crus cerebri, left side of pons, and lower and inner part of the left lobe of the cerebellum; also the left side of the upper half of the medulla oblongata, when it extends across the middle line, to include the right anterior pyramid. The left fifth, sixth, seventh, and part of the eighth nerves can be seen springing from the tumour. It is formed of minute dendritic villosities.

Dr. Ogle relates a case of softening of the chief part of the left cerebral hemisphere in connection with plugging of the left internal carotid artery; peculiar tunnelling, or canicu- lated state of the arterial plug, accompanied by a remarkable mouse-trap odour of the patient before death. The patient was fifty-two, had had painter's colic, but never rheumatic fever, or "fits" of any kind. His right arm was paralysed and subsequently the right leg. The urine was albuminous. After death, almost the whole of the central parts of the left cerebral hemisphere were broken down into a pulp extending as far onwards as the outer part of the optic thalamus, and corpus striatum, and downwards almost to the bar of the brain. The left internal carotid artery immediately before its division into its terminal branches, was found to be blocked up by a plug of firm fibrous material, closely adherent to the walls of the vessel. On opening this vessel the plug was found to be perforated by a fine canal, capable of allowing a pig's bristle to pass. The kidneys were in a state of granular degeneration.

The last case we shall notice is that of chronic meningitis in a case of supposed syphilitic disease of the bones of the skull, by Mr. Pick. The patient had been married 33 years, and until the last ten years had been quite well. Since then he had had fits of violent temper. He drank largely, and had lately lived ill. No history of syphilis could be obtained. He died very suddenly in St. George's Hospital, with symptoms of uræmic poison. The urine was observed to be albuminous. On examination the calvaria, especially of the back part, were found to be much thickened, and to present a porous and worm-eaten appearance. All over the surface of the brain was a uniform and diffused layer of solidified lymph, of a greenish colour, at least a quarter of an inch in thickness. From the condition of the effusion, Mr. Pick thinks it must have existed there some time, and he thinks, although we cannot see clearly why, that the disease was probably syphilitic in its origin, and that it had commenced in the bone. No mention is made in the communication as to the appearance of the skull bones.

In our next notice we shall treat of diseases of the respiratory organs, which occupy fifty pages of the *Transactions*.

Correspondence.

THE TRUTH ABOUT NICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—All that Dr. John Hawkins has written for and against Nice is only relatively true. He calls Nice the quarters situated next the river and in the neighbourhood of the sea. But this part of Nice is not the only one, is not the whole of Nice, just as the Strand cannot be said to be the whole of London.

I have passed nine winters at Nice, and five times in different quarters. The true climate of Nice you will find in the country parts, remote from the sea and from the river, in the different villas and gardens of the Quartiers St. Philip, St. Etienne, but principally Lazaret, Carabacel, and Cimies. It is to the latter and to its geological and climatical relations that Nice owes its ancient reputation as a delicious winter station for healthy persons, and as a harbour of health for those invalids who are suffering from certain diseases.

But most people think that you are not at Nice when you do not lodge in one of those fashionable quarters near the sea and the river, and that you do not enjoy the true life of Nice if you do not walk on the *Promenade des Anglais* in the fashionable hours, from two to five o'clock in the afternoon, and if you do not go to the balls and concerts. The very worst hours for taking walks on the one fashionable promenade are from the middle of the day, or say from one to two o'clock p.m. till eight o'clock at night, because then a disagreeable cold and sharp wind blows from the sea; whilst from nine to twelve o'clock in the forenoon are the warmest, most salutary hours, and most free from wind.

But in the morning you meet only a few walkers, mostly children, or all reasonable individuals; whilst in the afternoon the majority of the walkers are unreasonable, or mere pleasure seekers. A.M., you see Nature alone; P.M., art and fashion alone. Dust can be avoided, when those patients who fear it, or for whom it is injurious (as it is for all who suffer in the eyes, larynx, or chest), choose villas situated in the quarters farthest removed from the river and the sea; and do not go out in the town in the windy hours named, or only in their gardens or sheltered streets or roads.

By the bye, all the patients, who suffer from general or local irritability, especially of the eyes, throat, bronchial tubes, or who have tubercular or other diseases of the respiratory apparatus, do not form the true contingent for Nice visitors, and ought never to come to Nice. On the other hand, those suffering from rheumatism, gout, diseases of the skin, kidneys, or nerves, will not be really injured by dust, and may escape the wind if they follow the rules of the manner of life for invalids at Nice, that is to say: (*a*) Never go out without an overcoat; (*b*) Be at home half-an-hour before sunset (till eight o'clock, except when the sky is cloudy, as on dull days there is not so much wind or dust. As for the expenses, those who are not very rich should (*a*) First write to their future physician, or ask a friend, or procure a book on Nice, and seek the hotel that is least dear; (*b*) Not arrive in the evening, in order to be able to make a choice in the hotel; (*c*) Ask the physician which locality is the best for their constitution or health; (*d*) When single or two persons only go to a pension (boarding-house), when with a large family, then take an apartment; (*e*) When with weak stomachs take their own cook; (*f*) The balls and concerts can be as easily avoided as in large towns.

Finally, I think that the philippic of Dr. Hawkins is excellent, and should appear in the French papers, for the information of the authorities of the town, on whom the MEDICAL PRESS AND CIRCULAR has conferred a benefit by speaking the truth about what needs improvement.—I am, &c.,

G. P.

Nice, February 18, 1869.

Medico-Parliamentary Intelligence.

HOUSE OF LORDS—THURSDAY.

CONTAGIOUS DISEASES IN CATTLE.

Lord **LIFFORD** asked the Secretary of State for the Colonies whether it was the intention of Her Majesty's Government to ask Parliament to extend the operation of the "Contagious Diseases Act, 1866."

The Earl of **MORLEY** said the subject was under consideration, and a Bill would shortly be introduced on the subject, either in that or the other House of Parliament. The Bill would be mainly founded on the recommendations of the Committee of last year.

HOUSE OF COMMONS—THURSDAY.

CONTAGIOUS DISEASES.

Mr. **MITFORD** asked the First Lord of the Treasury if Her Majesty's Government would propose to Parliament any extension of the "Contagious Diseases Act, 1866," to places not mentioned in the first schedule of that Act.

Mr. **GLADSTONE** said that Government had under their consideration the course to be taken with respect to that Act, and would in a short time state the conclusion at which they had arrived.

MEDICAL AND EDUCATIONAL CHARGES (IRELAND).

Mr. **GREGORY** asked the Secretary to the Treasury whether, in accordance with the pledge given that the Irish Unions should be relieved of half the medical and the whole of their educational charges, it was the intention of Her Majesty's Government to add the deficiency of the sum voted last year for that purpose to the estimate of the present year.

Mr. **AYRTON** said he had made enquiry into the subject, and the arrangements adopted, as far as he understood, were that an estimate should be made at the beginning of the year of the sum that would be required to meet the charges in each of the Unions, and if at the end of the year that estimate was exceeded, the Treasury should not pay the excess, but if the expenditure was less than the estimate then the actual charge only should be paid by the Treasury. In accordance with that arrangement no application has been made to the Treasury for any further claim, and the subject has not been brought under their consideration.

FRIDAY.

RATING OF HOSPITALS AND OTHER CHARITIES.

Mr. **WHEELHOUSE** asked the President of the Poor-law Board whether it was the intention of Her Majesty's Government to take any step during the present Session, fully to exempt public hospitals, infirmaries, dispensaries for the sick, and endowed almshouses from liability to rating to the relief of the poor.

Mr. **GOSCHEN** replied that that was a very large question —a much larger one, indeed, than it appeared to be as put by the hon. member. It would be very difficult to confine any such exemptions to public hospitals, infirmaries, dispensaries for the sick, and endowed almshouses. The Sunday schools, for instance, had been omitted from the list; and again, there was the question of endowed schools. If they were to exempt endowed almshouses the question would arise whether endowed schools should not be admitted to a similar privilege. Then they came to the public building, municipal buildings, and county buildings. The question was, in fact, an exceedingly large and complicated one, and it was not the intention of Her Majesty's Government to take any steps in the matter this Session.

Gleanings in Medicine, Surgery, and the Allied Sciences.

SURGERY.

THE INJURIOUS INFLUENCE OF DRESSINGS IN AMPUTATION CASES.

DR. **BUROW** has already sought to prove in 1859 (*Deutsche Klinik*) that the dressings are the principal cause of the great mortality which follows amputations. He only lost one or two per cent. of his cases, although the statistics of Pauli indicate a mortality of 33 per cent. He attributes this valuable result to his leaving the stump exposed to the contact of atmospheric air. The skill of the operator goes for nothing, the operations being, in his clinical service, principally performed by his pupils. The following is his procedure :— healways, when possible, employs the tourniquet to compress the artery and vein together. He performs, as often as possible, the flap amputation. He does not excise the periosteum before sawing the bone. Ties the vessels with great care, and waits before closing the wound with two or three sutures until serous exudation from the wound has ceased. The patient being put to bed, a small cushion is placed under the stump, which is covered simply by a piece of linen, and ice is applied if pain supervenes. Towards the second or third day, swelling of the stump takes place, and if the sutures are cutting out they are divided and the inner extremity is left in its place. When the pus is observed to exude through the opening, the sutures are drawn out. It is necessary to clean away the secretion every day, and when the suppuration is not normal, to apply compresses dipped in alcohol and albumen.—*Deutsche Klinik.*

EXTENSIVE CANCER OF THE BREAST CURED RAPIDLY BY ACETIC ACID AND CREOSOTE.

DR. **MARGUTTINI** publishes the following case :—Marie Cossi, aged 55, has suffered for eight years from a tumour which occupies the whole of the left breast. For six years it remained indolent, then began to experience lancinating pains, the skin became red, the tumour became hard, and ulceration took place. On examination it was found that the ulceration divided the breast into two parts, it was sanguinolent, with raised hard edges, and the glands of the axilla were swollen. Dr. Marguttini prescribed the application of charpie soaked in the following mixture :—concentrated acetic acid, 15 grammes ; creosote, 3·50 grammes ; distilled water, 4·50 grammes. The treatment was followed out for six weeks, at the end of which period the patient visited the surgeon, who found to his great surprise a complete cicatrization of the cancer, and a thorough change in her general condition, the appetite had returned and the axillary glands had lost all their swelling.—*Ippocratico.*

CASE OF COLLOID CANCER DEVELOPED IN THE CONNECTIVE TISSUE OF THE PERITONEUM, AND EMBRACING THE ABDOMINAL VISCERA.

DR. P. F. **EVE** reports this case in the *New Orleans Journal of Medicine*, as having occurred in the person of a previously healthy planter, over 65 years of age. He received a fall, striking upon the nates and hip, and severely jarring his back and body. He complained of pain in the dorsal and lumbar regions, and want of full control over his lower extremities. He still continued, however, to do light work about the farm. After this he slowly declined, and in a year and a half an abdominal tumour could be felt which was thought to be scirrhus. Soon after several tumours could be felt, and he slowly sank, and died in about two years from the receipt of the injury. The autopsy revealed in the abdominal cavity about 16 pints of serum. The small intestines were greatly inflamed, with apparently impassable occlusion of the colon from enteritis. Besides three large tumours in the abdominal wall, there was a continuous colloid mass in the connective tissue of the peritoneum over the liver, stomach, pancreas, spleen, kidneys, bladder, and the whole length of the colon down to a portion of the rectum. On opening the abdominal cavity, nothing could be seen except the small intestines and the bladder, all the other viscera being embedded and obscured by the colloid mass. The omentum was adherent to and forced into the anterior tumour, which thus formed the largest of three tumours. The colloid character was plainly marked, was quite firm in places, and exuded a rather stiff jelly when pressed. The whole cancerous mass weighed about four or five pounds.

THERAPEUTICS.

INFLUENCE OF BILE ON THE SALT OF QUININE.

A **MIXTURE** of bile and of solution of sulphate of quinine produces a rapid and reciprocal decomposition, forming sulphate of soda and glycocholate of quinine with an excess of free glycocholic acid. The glycocholate of quinine presents itself as a dense resinous mass, insoluble at low temperatures in water or dilute acids, but soluble in ammonia and alcohol. Thus the salts of quinine may be absorbed by the stomach, if they pass into the intestines they are lost in consequence of the insoluble nature of the compound resulting from their admixture with the bile—*Giornale di Medicina.*

PAUPERISM AND CRIME IN THE METROPOLIS.—The adjourned conference on pauperism and crime in the metropolis was held on Thursday at the rooms of the Society of Arts, Adelphi, the Rev. Dr. Barry, Principal of King's College, in the chair. The following resolutions were carried :—"That this conference recommends the Council of the Association for the Prevention of Pauperism and Crime in the Metropolis to use their strennous endeavours to procure by legislation and social action an organised communication between the London charities."—"That an official register of all applicants for relief in the metropolitan districts is essential for the prevention of imposture, the previous application of charity and the efficient relief of distress."—"That it is important to obtain an Act of Parliament for the registration of charitable societies on general principles as that of friendly and provident societies, and also for the due audit of their accounts, and for the publication of their balance-sheets on a prescribed uniform plan."—"That the requisite steps for carrying the resolution into effect be referred to the Council of the Association for the Prevention of Pauperism and Crime in the Metropolis."

APOTHECARIES' HALL.—At a Court of Examiners, held on the 25th ult., the following gentlemen having passed the necessary examinations, were admitted Licentiates of the Society of Apothecaries, viz. :—Messrs. Arthur Cæsar, of the Tower Hamlets Dispensary; C. D. H. Drury, of Newcastle-upon-Tyne; E. H. Hugo, of Brompton, Kent; and J. F. Smith, of Martin, near Sleaford. And at the same Court the following passed the primary professional examinations, viz. :—Messrs. Horace Gooch Button, of Guy's Hospital; Percival Kingsford, of Guy's Hospital; and Francis Warner, of King's College Hospital.

NOTICES TO CORRESPONDENTS.

MR. M. D. CROFTON.—Your letter shall appear in our next.

SURGEON ALCOCK (Portsmouth).—Proof of your paper *in extenso*, shall be sent you, when the engraver has finished the etching.

MR. THOMAS FALCON (Leeds).—Many thanks.

MR. COTTER.—Thanks; the journal shall be sent regularly to the address in Jamaica.

DR. TOOGOOD DOWNING (Bath).—Your second letter to hand; shall appear in our next if possible.

MR. HOLMES COOTE.—"On Polypi of the Rectum" received, and shall appear in an early number.

NITROUS OXIDE AND CHLOROFORM.

To the Editor of the Medical Press and Circular.

SIR,

I shall feel obliged if you will allow a small space in the MEDICAL CIRCULAR, to enquire as to the effects of the nitrous oxide gas, There are so many conflicting opinions as to the safety or otherwise of its inhalation. In this town the advertising dentists profess to use it, as being *free from danger*, and chemists and others use it on most occasions without the supervision of a surgeon. Is it safe to do so? The Odontological Society's Report, whilst admitting that thousands of teeth have been extracted under its influence with safety, show that in some cases there is probability of unpleasant results. I have attended several cases where the operation has been painless, and without any apparent inconvenience. As far as I can judge here, the medical world have not taken much interest in the matter, and prefer chloroform. Will you favour me with your opinion on the subject?

Your constant reader and subscriber,

Brighton. MOLAR.

We entertain a very strong opinion against the applicability of nitrous oxide as an anæsthetic for general use in private practice. It is true that in the skilful hands of the surgeons to the Dental Hospital, it has as yet been unattended by any casualty, but very little argument for its use in private hands can be deduced from this fact. In the first place a cumbersome and expensive apparatus is essential for the generation of the gas, and under no ordinary requirement of private practice would the cost and trouble of its use be repaid. Secondly, the period of insensibility is so short as to be practically useless, except for dental operations, and, indeed, not even for extraction of stumps, or any of the more prolonged procedures in dentistry. Thirdly, the objections to chloroform on account of its causing excitement and vomiting and subsequent giddiness, apply with increased force to nitrous oxide, inasmuch as it frequently causes violent opisthotonos, and not uncommonly results in vomiting.

Lastly, the action of nitrous oxide is undoubtedly that of an asphyxiant and not an anæsthetic at all; and the question for dispute is whether surgeons will venture on smothering a patient into insensibility even though it may be done with impunity. The appearances of the patient under inhalation are those of imminent death, and certainly sufficiently alarming to create an insuperable first impression against the risk. We hear nothing of the sequelæ of the operation, but it can hardly be supposed that impending suffocation can be produced without some ill-result in the system. The best that can be said of nitrous oxide is, that it is more rapid than chloroform or ether, and that fatalities from its use have not yet been publicly known. In every other respect it is inferior to other anæsthetics. We entertain the strongest suspicion that its use in private practice is nothing in most cases but a false profession.

ON THE MODE OF ACTION OF THE CHOLERA POISON.

By **Arthur Ernest Sansom**, M.D. Lond., M.R.C.P.,

Physician to the Royal Hospital for Diseases of the Chest, City road.

(Continued from page 158.)

Having traced the cholera germ to its transmission to the human organism, we have now to enquire concerning its action and effects. It is, at first sight, likely that these will vary (1) with the quantity of poison absorbed. So it is rendered very probable that the frequency of diarrhœa during times of cholera is due to the ingestion of cholera germs in quantities insufficient to produce the more marked effects (2) with the phase of development of the cholera germ. Such is rendered probable, not only by the experimental evidence already quoted, but by the indications which statistics afford of the diurnal variations in morbility and mortality of populations under the same local conditions, (3) with the receptive condition of the organism.

The circumstances which predispose to the prevalence and virulence of a cholera epidemic are shown for the most part to be those which imply a combination of these conditions. For instance, dirt, squalor, and thickness of population imply the prevalence of the nitrogenous soil in which the cholera germ tends to propagate, the comparative facility of transmission of the germs from individual to individual, and the want of hygienic means, which depresses the vital powers in the case of this as in the case of any other disease.

Statistics show that men and women are almost equally prone to the effects of the poison, but *old* women are more liable to them than *old* men. The fatality of the disease is slightly greater in males than in females, except at the procreative ages twenty-five to forty-five. It does not appear, therefore, that any special condition of systemic debility predisposes to the morbid effects of the cholera germ, except *age*, which certainly has a marked influence. According to Dr. Farr, "human life loses the power of resisting the zymotic life of the cholera epidemic year by year after puberty." Mortality increases as age advances. In this regard, though cholera resembles fevers, it differs from variola, scarlatina, diphtheria, and rubeola. But now comes the striking fact, that of those individuals to whom the poison is transmitted in equal degrees and under like conditions, only a portion of them suffers from morbid effects. This fact seems to stand out more prominently than in the cases of other infectious diseases. For instance, the whole of the members of a family will be drinking the same contaminated water; in some of the members cholera may be manifested and may prove fatal, in others it may occur in varying degrees of severity, and some may escape altogether. It follows that there are certain conditions which excite, and certain others which prevent the morbid efficacy of the cholera germ. The question, what are these conditions respectively? may be difficult, though perhaps not impossible to answer. It will be more convenient to defer the enquiry until we have considered what are probably the first effects of the germ upon the economy?

I have said that in by far the greater proportion of cases, if not in all, the germ enters the system by the way of the alimentary canal. How long does it require to be there latent before its effects are manifest? According to Dr. Macpherson,[*] cholera may break out in eight or ten hours from the earliest possible exposure to its sources. Snow[†] gave its period of incubation as from twenty-four to forty-eight hours.

It is not likely that any marked change in the phases of development of the cholera germ can take place in the short periods of time named, it is therefore most reasonable to suppose that the germ when swallowed is at its maximum of potential efficacy, and commences its morbid action just as a medicinal purgative would, or as those noxious emanations which produce nausea and symptoms of intestinal irritation following so closely as to allow little room for doubt as to the logical sequence of cause and effect. Absorbed into the alimentary canal, the first effects are manifest either upon that canal or upon the structures in immediate relation therewith. These are nausea, oppression at the epigastrium, diarrhœa. Such symptoms we know by analogy may result from irritation of the mucous membrane of the intestinal canal.

---

[*] *Medical Times and Gazette*, July 13th, 1867.

[†] "On the Mode of Communication of Cholera." Second Edition. P. 16.

It is, I consider, rendered very probable that the invasive symptoms of cholera may occur for a long period before the manifestation of the specially characteristic symptoms of the disease. In forty-one of the cases observed by Dr. Sutton, the symptoms of invasion varied in duration from twelve hours to eight weeks. It is probable, therefore, that though the cholera germ is quickly an irritant of the gastro-intestinal mucous membrane, it may proliferate and accumulate within the body before manifesting its characteristic effects.

Now comes an important consideration. I think it can scarcely be doubted, since it has been vouched for by so many good and true men, that those measures which have, according to foregone experience, arrested symptoms of ordinary diarrhœa, have also arrested that form of diarrhœa which is frequently the precursor of true cholera. Why have they done so? Let us briefly glance at the means which have, according to the testimony of experience, proved thus efficacious, and consider them in reference to the hypothesis of an organized cholera poison. We may class these as—

1. Antiseptics, as the sulphites, carbolic acid, creosote, &c.
2. Acids, particularly sulphuric acid.
3. Mineral astringents, as acetate of lead, sulphate of copper, &c.
4. Mineral salts not astringents, as calomel.
5. Vegetable astringents, the chief ingredient of which is tannin.
6. Chalk and aromatics.
7. Opiates.
8. Purgatives.

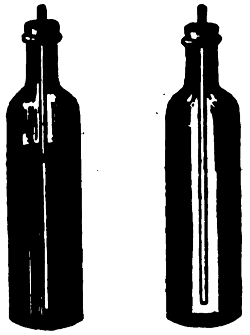
The operation of the first class, antiseptics, we need not stay to discuss. It will probably be admitted that they arrest the vitality of the septic particles, whether these be the prime causes of the disease, or the induced products of fermentation within the body, which give rise to that irritation the result of which is diarrhœa.

Of the remaining agents the *modus operandi* is, at first, not so easy to explain. On this point I have made some observations which, imperfect as they are, cannot fail, I think, to be of some interest. The question which I set myself to consider was this: Is it possible that some of the agents which have been used successfully in the treatment of diarrhœa may have had an action similar to, or analogous with antiseptics, though they have not been so considered? Antiseptics stop the growth of organized germs: are any of the other agents employed capable of a like action?

I endeavoured to investigate the effects of various agents upon fermentation—a process, the essence of which is the growth and multiplication of vegetable particles. To do this I employed the following means. Having obtained a series of bottles, each of the same capacity, I adapted to each a cork, through the centre of which passed a tube of the same calibre in all, one end reaching nearly to the bottom of the bottle, and the other rising an equal height (about an inch) above the corks. Into every bottle of the series were put twenty-five grains of cane sugar, and a quantity of yeast (two drachms) taken from the same sample. One of the series (A) was filled with pure cold water, into each of the others in addition, one of the following ingredients was added:—

B. Liquor potassæ, 5 minims.
C. Sulphuric acid, 1 tenth of a grain.
D. Tannic acid, 5 grains.
E. Acetate of lead, 5 grains.
F. Liq. hydrargyri bichloridi, ½ a drachm.

The corks and tubes were now adapted, and the whole were plunged into a vessel of water at a temperature of 100 degrees Fahrenheit. The external influences, therefore, to which all were exposed were absolutely identical. It will be readily understood that on the fermentative process occurring the accumulation of carbonic acid at the upper part of the bottles would drive through the vertical tube the fluid contents. Observation, therefore, of the rapidity of emptying, and of the state of fulness or emptiness of the bottles (see Fig.), would be an index of the rapidity and extent of the fermenting process. Now although, of course, the method was not intended to give results of absolute precision, still each bottle being subject to identical external influences, the results were strictly relative, and admit of a close comparison. The following points were noted:—



1. In bottle A fermentation rapidly commenced.
2. In bottle B it also rapidly commenced, and at the end of an hour even more fluid was displaced than in A.
3. In D, fermentation was slightly retarded.
4. In the remainder there was no evidence of any fermentation whatever.

After the lapse of twelve hours, the bottles being again examined, the following were the results:—

A and B were completely empty—*i.e.*, the fermentation had caused the displacement of the whole of their contents.

D was nearly empty; whilst in

E a very small quantity of fluid was displaced; and in

C and F the fermentative process had been wholly arrested.

It was therefore evident that (1) in an alkaline solution fermentation occurred even more rapidly than under ordinary circumstances; (2) that the presence of a minute amount of sulphuric acid completely arrested all fermentation. I think this fact is very powerful to explain the action of dilute sulphuric acid in restraining diarrhœa and the initial symptoms of cholera. Further observations in this direction are not wanting. Vibrios cannot live in acid solutions. Is it not probable that these circumstances may explain what have been sometimes called the "conditions of idiosyncracy" predisposing to an attack of cholera? Thus, suppose the cholera-genic molecules be absorbed into a stomach in which there is a vigorous outpouring of the gastric juice; they are at once killed—they are rendered innocuous. Suppose, on the other hand, they find access to the stomach at a time when its contents are deficient in acidity, or when the general state of the body is one of the preponderance of an alkali; then occur the manifestations of the toxic power of the germs, and the effects of their proliferation in inducing the phenomena of the disease. The observations on fermentation indicated (3) that the metallic salts, acetate of lead, and bichloride of mercury, had a great influence upon the fermentative process. The influence of the latter was, however, by far the most profound, for after keeping the bottles prepared as before indicated for several days, I found that whereas the process of fermentation did take place to a considerable extent in the case of the fluid containing acetate of lead, no fermentation whatever was manifested when bichloride of mercury was present. The efficacy of the former, therefore, must be sought partly in its astringent, partly in its antiseptic character. The behaviour of bichloride of mercury, however, may help in some degree to explain the value of calomel in diarrhœa (which has been frequently attested). Apart from its power of mechanical elimination by purgation, some of it, converted by the fluids of the body into the soluble chloride, may act as the powerful antiseptic which it is proved to be.

The behaviour of tannin gave me some surprise, for in the case of such a deoxidising agent I anticipated that some pronounced effect would be manifest. It is obvious that if we accept the analogy of fermentation with septic conditions, tannin is not an antiseptic. How, then, can we explain the action of vegetable astringents in the arrest of diarrhœa? First, is the premiss allowable that astringents are *per se* efficacious? On this point the following is the testimony recorded in an admirable *résumé* of Remedies for Diarrhœa recorded in the *Medical Times and Gazette* for July 28th, 1866:—"It must be observed that these remedies (astringents) are seldom given without opium, and that they do not appear superior to sulphuric acid; certainly not so good for popular use." Granted, however, that they have an action of some practical value, we may find an explanation of this in their property of constringing the capillary vessels.

The action of opium in diarrhœa harmonizes with almost any theory of causation. Allaying spasm and inducing rest, it tends to a restoration of healthy eliminant action. "In giving opium, the practitioner does what the surgeon does when a patient with irritated bladder cannot pass his urine; and what the accoucheur does when a woman is plagued with inefficient uterine action. Opium rests a weary colon, and allows it time to discharge its duties with vigour."*

Chalk with aromatics being an alkaline remedy, cannot, as before shown, have any action in arresting the vitality of germs in a fermenting body; but it may well be supposed that they may act mechanically, involving with their own the septic particles, and being carried through the economy.

Lastly, Purgatives.—If the irritant germs produce their effects wholly and solely by their presence in the alimentary canal, the use of purgatives both in diarrhœa and cholera stands upon a very sound basis. Their efficacy in arresting diarrhœa due to a simply irritant action can hardly be doubted by practical men. Of their utility, however, at the stage when the more simple symptoms are being accompanied by the characteristic signs of cholera, the voice of experience seems to speak with a sound of condemnation.

If we could adopt the view—(1) that when the existing germs are entirely or chiefly irritating the gastro-intestinal mucous membrane, and an aperient being administered, these are got rid of, and the disease the consequence of their presence becomes relieved, but (2) that by their more prolonged influence, or by their existence in greater quantities, or their multiplication in a more rapid manner, they induce local lesions, which remain after the first cause is removed; or that, besides being local (intestinal) irritants, they become a poison capable of absorption into the blood: then purgation is not only useless, but mischievous—some solution might be given of existing discrepancies. Dr. Johnson, however, who maintains so strongly the value of purgatives in cholera, asserts that the poison of cholera is wholly a *blood*-poison. I cannot but think that on these bases his theory and practice are at variance. If he believed that the poison was a gastro-intestinal irritant, and purgation removed it, I could understand his position; but to endeavour by a purgative to remove a subtle venom from the *blood*, seems to me a proceeding very difficult logically to defend.

The question which presents itself may be thus expressed: Is the cholera-germ a gastro-intestinal irritant —or a blood poison—or a combination of both? To investigate this I shall consider first the probable mode in which is produced the flux from the bowels, and in connection with this inquiry I shall record some experiments which I have made on fermentation taking place within the living body.*

(*To be continued.*)

CASE OF CONGENITAL MALFORMATION OF THE ŒSOPHAGUS.

By Thomas Annandale, F.R.S.E., Lecturer on Surgery.

On the evening of Thursday, the 28th of October, I was asked by Dr. Thomson, of Teviot Row, to see with him an infant thirty hours old. The patient—a first child—was born at the full time. Both parents were young, healthy, and well formed, and the mother's labour was perfectly natural. The infant at birth presented no external malformation, but it was noticed that it was several moments before it breathed, and when respiration became established it was at times thick and laboured. It was also particularly observed by both Dr. Thomson and the nurse, that when the child was fed for the first time (with milk, and by means of a spoon), the fluid only remained down a few seconds, and was then returned through the nostrils and mouth with a sort of spasmodic jerk. The infant passed the ordinary meconial fluid by the rectum two or three times, but no natural fæcal matter ever passed away.

Repeated and careful attempts were made to feed the patient, but the fluid returned as at first, and the nurse was quite sure that none of it passed into the stomach.

Having first witnessed an attempt to feed the child, and watched the peculiar hurried respiration, I proceeded to make a thorough examination of the external aspects of its head and neck, but could detect no abnormality. I then passed my finger into the mouth, and down into the throat beyond the epiglottis, but could still feel no malformation. Retaining my finger in the throat, I passed along it into the œsophagus a No. 8 elastic catheter, which slipped readily down the canal for a distance of nearly an inch from the top of the larynx. Beyond this point the extremity of the instrument would not pass, although it could be freely moved as if in a pouch or dilatation of the canal. I withdrew the catheter, and again re-introduced it, but with the same result; and I also tried to pass a No. 4 instrument, but its point was arrested as before.

At the consultation on the case Dr. Thomson and myself expressed a decided opinion that the canal of the œsophagus was completely obliterated at the seat of obstruction. The feasibility of an operation was discussed, but we both agreed that as there was evidently some abnormality in connection with the air-passages, and also that as there could be no certainty in regard to the condition of the canal below the obstruction, operative interference was not justifiable.

---

* *Medical Times and Gazette, loc. cit.*

* I am not quite sure that a portion of my last communication (p. 157) is not capable of a construction other than that which I intended. For example, in mentioning the views held by Beale, Pacini, and Hallier, I did not intend to imply an agreement between these observers as to the causation of cholera. I merely meant that they were unanimous in ascribing to a material of extreme minuteness, and possessed of *living* powers, an agency in the production of zymotic disease. I did not mean to imply that Prof. Beale held to the "fungus theory" of cholera causation, or held any other community with the other observers. The germinal matter efficient in cholera may be derived from the animal world, or from the vegetable. My further remarks are intended to convey the idea that it is impossible for us to logically determine *now* whether it is from the one or from the other. I should be sorry indeed to do an unwitting injustice to Professor Beale (holding, as I do, his opinions in the very highest respect), and to ascribe to him by implication views which his published writings do not warrant. Again, when I say that "germinal matter" is vested with vital powers "by the will of the Creator," this is rather *my view of his view*. I may be wrong in my inference.

The infant died on Friday, at half-past four o'clock a.m., having lived forty-eight hours.

A *post-mortem* examination was made on the following day. The neck, chest, abdomen, and pelvis, and their contents, were carefully examined, and found to be quite normal, with the exception of an interesting malformation of the œsophagus and trachea.

A more careful dissection of these parts showed that the upper portion of the œsophagus was dilated, and terminated in a rounded blind pouch (Fig. 1, C; Fig. 2, B), 3-10ths of an inch above the bifurcation of the trachea. The entire length of the upper portion of the canal, measuring from the cricoid cartilage to the extremity of the cul-de-sac, was 6-10ths of an inch. The lower end of the œsophagus (Fig. 1, E) was normal and pervious from the stomach to a little above the bifurcation of the trachea. At this point it was so intimately adherent to the posterior wall of the trachea, that the two could not be separated, and it appeared as if a fusion of the walls of the two canals had taken place (Fig. 2, D). On laying open the anterior wall of the trachea, the lower end of the œsophagus was seen to open into its posterior wall, a little to the left of the middle line, 3-10ths of an inch above the bifurcation, and the same distance below the termination of the cul-de-sac. This opening (Fig. 1, D) was the size of a crow-quill, and its anterior margin was surrounded by a semi-lunar fold of mucous membrane. The œsophagus between the cul-de-sac and the upper part of its lower end was merely represented by a few muscular fibres.

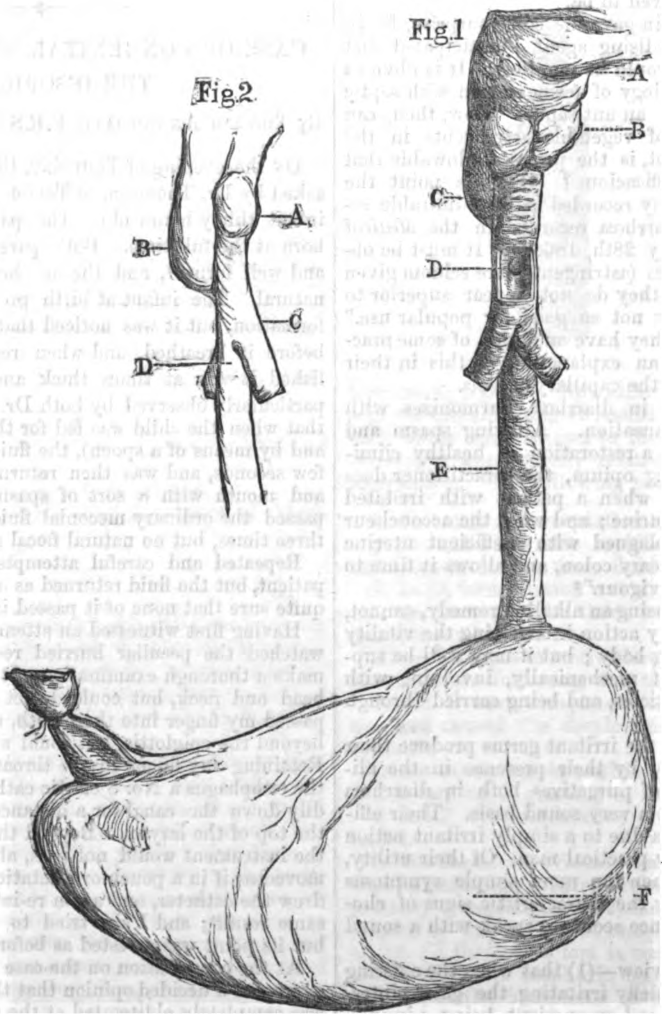


Fig. 1.—A, Hyoid bone.
B, Thyroid gland.
C, Dilated œsophagus terminating in a blind pouch.
D, Orifice of communication between the lower end of the œsophagus and the trachea (a portion of the anterior wall of the trachea has been removed to show this).
E, Gastric end of œsophagus, normal and pervious.
F, Stomach.

Fig. 2.—A, Thyroid gland.
B, Dilated œsophagus and cul-de-sac, viewed laterally and slightly from behind.
C, Trachea.
D, Lower end of œsophagus, merging into posterior wall of trachea.

Remarks.—The literature of this country does not, so far as I have been able to ascertain, contain a description of any case similar to the one just related. Cases of congenital malformation of the œsophagus—such as Meckel refers to, as described by Roderer—have been found in conjunction with other defects of the alimentary canal; but in the present instance the whole canal, with the exception of the œsophageal malformation, was normal in form and arrangement.

The particular kind of deformity met with in this case is obviously extremely rare. Still, a few cases very similar to it have been recorded in some of the Continental treatises. Vrolik, in his 89th Plate, figures the œsophagus of a new-born infant, in which that tube terminated a little above the bifurcation of the trachea in a cul-de-sac. Commencing again immediately below to pass down into the stomach, the œsophagus opened into the trachea by a roundish oblong foramen. Albers[1] figures a case in which the occlusion of the œsophagus was still more strongly marked, for not only did that tube end in a cul-de-sac, but the part immediately below was a solid thread, which was continued inferiorly into the lower and pervious gastric end of the œsophagus. A very similar case has also been described by Scholler.[2]

M. Sedillot,[3] in his chapter "De la Gastrotomie," states that these malformations may be divided into three classes: (1) complete *interruption* of the canal of the œsophagus; (2) atrophy and obliteration; (3) solution of continuity with a communication between the lower end of the œsophagus and the trachea. M. Sedillot quotes freely from an interesting paper by M. Andral, "On the different Congenital Lesions of the Œsophagus, which cause New-born Infants to die from Starvation." In this paper M. Andral says, that there are cases in which the upper end of the œsophagus ends in a cul-de-sac, there being only cellular tissue between the latter and the stomach. In other cases the œsophagus, in its whole length, is represented by a plain cord. The same author refers to a case reported by M. Martin, in which the only trace of the œsophagus was a canal some lines in length, which terminated at the side of the pharynx in a cul-de-sac, but immediately above the origin of the bronchi the trachea presented an opening the size of a small quill, which passed into a membranous elastic tube that communicated directly with the stomach. Another case, reported by Professor Levy, is related, in which the upper end of the œsophagus was dilated, and terminated in a cul-de-sac. The lower extremity of the canal opened into the trachea a little above its bifurcation. A curious circumstance in connection with this case, the nature of which was diagnosed during life, was, that the child, which lived four days, lost exactly one and a half pounds in weight from the time of its birth to its death.

Although, in the case related above, the dilatation and obliteration of the canal of the œsophagus were distinctly diagnosed during the life of the patient, examples of this form of congenital malformation cannot be considered to be of much practical importance to the surgeon, owing to their extreme rarity, and also to the fact that they do not admit of operative interference. The dissection of the malformed parts in this case well showed how unsatisfactory any operation would prove in such deformities. The peculiar character of the infant's breathing led both Dr. Thomson and myself to suppose that there was some abnormal communication with the air-passages, but the nature of this communication was only determined by the *post-mortem* dissection.

In reference to operative interference in such malformations, M. Sedillot remarks:—"Dans tous les cas où l'œsophage est simplement oblitéré, atrophié ou interrompu, la gastrotomie donnerait l'espérance de sauver l'enfant sans autres accidents que ceux de l'opération elle-même. S'il existait une communication du bout inférieur de l'œsophage avec la trachée, on pourrait craindre que les substances portées dans l'estomac arrivassent par regurgitation dans les voies aériennes; mais l'étroitesse de l'orifice anormal et sa tendance naturelle à se fermer par sa non-raison d'être, devraient rassurer contre l'éventualité de cet inconvénient, que rien ne permettrait *à priori* de soupçonner."—*Edin. Med. Journ.*

CONTRIBUTIONS TO CLINICAL SURGERY AND MEDICINE.

By William Hargrave,

Professor of Surgery, Royal College of Surgeons, &c.

I.—INJURY TO THE LUMBAR REGION OF THE SPINE, WITH SOME PECULIAR SYMPTOMS.

II.—THE EXTRACTION OF NEEDLES: ONE WAS SUCCESSFUL UNDER THE ADMINISTRATION OF CHLOROFORM CARRIED TO ITS EXTREME EXTENT, THE OTHER WITHOUT IT.

(Cases taken by Mr. Donaldson, Resident Pupil.)

INJURY TO THE SPINE IN THE LUMBAR REGION.

Under the care of Dr. Hargrave.

Michael C., aged eighteen, residing in Blackrock, was admitted into the City of Dublin Hospital, Oct. 13, 1868.

Previous History.—Was working in a hay-loft and fell down through a trap-door, about twelve feet, on some brick paving; appears to have fallen first on his loins; got a very severe shock; was carried home, where he vomited a good deal, and then fell asleep. After sleeping for about two hours he awoke, with great pain across his loins and hip, which continued getting worse until the following day, when he was admitted into hospital. On admission: complains of acute pain across the loins and hips; cries out on being moved; passes his urine with some difficulty. Since the fall has lost sensation along the front of the left thigh and leg, nearly down to the ankle. Complains of pain in one particular part of the lumbar spine. A mustard plaster was applied to the loins, which gave him a good deal of relief.

Oct. 14th.—Pain greatly relieved, but complete anæsthesia still along the front of left leg. To be cupped to ℥ij. from the lumbar region.

15th.—The cupping has given him much relief; the motions of the limb are perfect, except extension, which he can only accomplish by placing the foot of the right leg under the tendo Achillis, close to the os calcis, and shoving it down to the full extension. Prescribed a liniment, sap. co., with tra. nucis vom., chloroform, and aconite for the loins.

16th.—Pain relieved by the liniment; no change in the anæsthesia or power over the limb.

17th.—Two moxas, the size each of a shilling, to cause vesication, but no slough on the lumbar region.

18th and 19th.—The moxas have benefited all the symptoms; he is regaining some power over the extensor muscles of the thigh and leg; anæsthesia diminishing.

℞ Proto iod. hydrarg. vir., gr. vj.
Submur. hydrarg., gr. iij.
Pulv. opii, gr. i.
In pil. vi., st. i., mane nocteque.

Also,

℞ Iodid. potass. ʒi.
Liq. potass., ʒi.
Aquæ lauro cer., ʒi.
Aqua dist. ad., ℥viij. ♏
Ft. cochl. ampla duo, ter in die.

20th.—Continues much the same way. Takes his pills and mixture.

23rd.—Complains of great numbness of the limb. Ordered to envelope it in cotton wadding.

24th.—A good deal relieved by the cotton wadding; is beginning to walk a little on the limb.

29th.—Little change; walks, but with difficulty, on the affected limb every day; keeps it enveloped in cotton wadding. Ordered—

℞ Ext. nucis vom., gr. vj.
Ext. gentiani, gr. xij.
Fiant pil. vi., capt. i., mane nocteque.

31st.—No benefit from the nux vomica. The following mixture prescribed:—℞ Decoct. arnica mont., tr. ejusdem, tr. card. co. spir. chlorof. iodi potassæ, gr. xxx., in the eight-ounce mixture, ℥i., ter in die.

[1] Forster, Missbildungen des Menschen. Jena, 1865.

[2] Forster. Plate xxiv., figures 20, 21, 22.

[3] Contributions à la Chirurgie, vol. ii., p. 405. 1868.

November 4th.—Walks about pretty well, but still feels much numbness of the left limb.

7th.—Left hospital this day of his own accord.

This patient was readmitted to-day, the 12th November, complaining of great pain in the lumbar region; great numbness along the front of the thigh and leg; total inability to use it. All the symptoms affecting the left limb were more aggravated than when first admitted, Oct. 13.

The arnica mixture was repeated, and the bromide of potash substituted for the iodide of potash.

14th.—Numbness continues; complains of a looseness (as he calls it) about the knee-joint; has lost a great deal of the power to extend the leg.

15th.—Complains of pain running down along the outer and inner side of thigh. Ordered: the most painful part to be well streaked with nit. argenti, and to continue his medicine.

16th.—Appears to have much better power to extend and flex the limb. To continue mixture, and a warm flannel cloth to be wrung out of boiling water and applied to the lumbar region, as hot as he could bear it, for half an hour, covered with oiled silk, three times a day.

24th.—Has continued the application of the flannel and his medicine, and appears to have much better power over the limb.

In addition to this treatment, galvanism was applied to the loins and anterior crural nerve, under which he rapidly improved, and left the hospital, December 15, with all the functions, power, and sensation of the left limb restored to its normal state, having been under observation and treatment forty-eight days.

From the symptoms presented by this case the lesion in the lumbar region must have been the result of not alone concussion, but also some sanguineous effusion, some small clot of blood pressing upon the posterior roots of the lumbar plexus, and explaining the partial anæsthesia referred to such an extensive portion of the anterior part of the left inferior extremity, from near Poupart's ligament to within a short distance of the ankle-joint. Why should not this symptom be more general, and not confined solely to the anterior aspect of the limb? Is it possible that there was only partial pressure upon the sensitive roots? The symptom would justify entertaining this opinion. Again, as to the effect of the nervous lesion over the locomotive system. The remarkable phenomenon observed was the patient having complete power of flexion over the inferior extremity, with the inability to extend it, which could only be effected by the patient placing the foot of his right leg under the tendo Achillis of the left one, immediately above the os calcis, by which means he slowly restored it (by pushing) to the extended position; on other trials to extend the limb after being flexed he could only succeed by rotating the thigh powerfully outwards, and could then extend the limb by a powerful effort without the assistance of the left one.

On re-admission, after the lapse of five days, this patient's condition was worse than when first admitted, as regards both the anæsthesia, with no power of extending the limb, but experienced less pain. The treatment which restored this young man to perfect recovery can be recapitulated as follows:—Small cuppings over the loins; the application of superficial moxas; application of very hot flannels at a high temperature on the lumbar region; the administration of bromide of potash, in the decoction of arnica montana, with the application of galvanism. From the success of this treatment whatever effusion was caused by the accident had been completely absorbed. This patient also complained much of pains about the knee-joint, and extending along the inferior part of the thigh, both in the external and internal aspects, which I do not consider as the result of inflammation, but of a nervous character. For their relief I have found permanent benefit from what I consider a potential cautery, the nitrate of silver; applying it in parallel lines of two or three in number, and the breadth of the little finger, and four inches long, so as to discolour the skin to a dark brown colour. The same application for similar symptoms about the elbow and ankle has afforded more relief than either liniments or blisters.

(To be continued.)

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. Thornley Stoker, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

COOMBE LYING-IN HOSPITAL, DUBLIN.

Some Cases of Ulceration of the Os Uteri treated by the application of Carbolic Acid.

(Under the care of Dr. Roe.)

Dr. Roe has been for some time in the habit of using carbolic acid as a local application in cases of ulceration of the os and cervix uteri, and has found it to yield results superior to any other topical treatment which he has tried. He has used it in cases where the whole round of other applications has been unsuccessful, and always with the most happy results. He agrees with Dr. Roberts, of Manchester, who last year drew the attention of the profession to the subject, in considering it a caustic, which, as regards its severity, may take intermediate rank between the nitrate of silver and strong nitric acid, besides acting as a disinfectant, a matter of no small importance in these cases. Dr. Roe does not use it in as strong a form as Dr. Roberts, and does not consider the strong acid necessary in very superficial ulcerations. A mixture of one part of the strong acid with two of olive oil seems to answer all ordinary purposes; but in cases of very deep ulceration the use of the strong acid may be called for. In such cases Dr. Roberts desires the acid to be liquified by the addition of a very small quantity of water. This has not been found to answer the purpose in the Coombe Hospital, but it has been there discovered by Mr. Weir, that the addition of a few grains of camphor will dissolve the acid, and will, moreover, prevent it again becoming solidified, even at a freezing temperature.

The application of the carbolic oil to the os uteri is best effected by soaking a little cotton wool in the liquid, securing it by a string, and introducing it through a speculum, the string being left depending out of the vagina, and the patient being directed to pull it away on the second day. This procedure is repeated in ordinary cases about twice every week. If it be desired to apply the acid to the cervical canal, it may readily be done, by passing into it a gum elastic catheter smeared with the carbolic oil.

The following cases, taken at random from a great number, are fair examples of the success of the treatment.

Case I.—Mrs. P., æt. 35, married ten years; has one child seven years old. Came under observation last December, suffering from headache, loss of appetite, great pain in the back and loins, and shooting pains through the pelvis. She complained of great pain during intercourse, menstruated very scantily, and had a profuse muco-purulent discharge. On examination the cervix was found enlarged, a discharge of albuminous matter from it, and all the symptoms of endocervicitis. The os was abraded of epithelium, vivid red in colour, and bled freely when touched. The nitrate of silver was applied to the os, and sulphate of zinc points introduced into the canal of the cervix; these not giving relief, iodine and other remedies were tried, but very slight benefit resulting, the application of the carbolic oil, both to os and cervix, was commenced early in February; it was used every third day for about a month, when the woman was quite recovered. In this, as in all the other cases, the patient was treated by tonics and aperients, in addition to the local use of the acid.

Case II.—Mrs. S., æt. 28 years, seven years married, has three children, the youngest two years of age; applied for relief last January, complaining of pains in the left iliac region, pain during defæcation and intercourse, constipated bowels, irritable bladder, &c., &c. Examination revealed an ulcer on the posterior lip of the os uteri, extending into the cervical canal, the os and cervix being soft and tender to the touch, and the ulcer secreting pus streaked with blood. Treated by tonics and aperients, and by the local use of the carbolic oil, this patient made a rapid recovery, the ulcer being completely healed, and the attendant symptoms relieved.

Case III.—Mrs. N., aged twenty-three, two years married, and having a child ten months old, which she was nursing, came to the hospital about the end of January, suffering from iliac pains, leucorrhœa, dyspepsia, &c. When examined she was found to be suffering from vaginitis. The os uteri was denuded, vivid red, and granular. The cervical canal was apparently healthy. She was put upon tonics and aperients, the carbolic oil was applied twice a week in the usual way, and she was quite recovered at the end of February.

SURGICAL SOCIETY OF IRELAND.

Friday Evening, February 19.

Dr. Labatt, senior member of the Royal College of Surgeons in Ireland (present), in the chair. Present—Messrs. Brassington, W. T. Stoker, Leech, Minchin, H. Kennedy, Murdock, J. R. Kirkpatrick, Grimshaw, R. N. Willis, A. H. Marks, Mapother, H. G. Croly, Isaac Usher, Wharton, Roe, Purcell, H. H. Stewart, Ferguson, R. P. White, D. B. Hewitt, R. A. Moore, W. D. Moore, C. F. Moore, C. Benson, J. H. Benson, W. M. Peebles, 81st Regiment (by Dr. Benson), W. Stokes, jun., C. Fleming, M. Collis, J. G. Beatty, R. Fennelly, A. H. Jacob, Stoney, A. Robinson, Darby, Hargrave, E. Hamilton, T. MacSwiney, J. Tufnell, B. J. McDowell, F. McDowell; Drs. Costello and Tobin, visitors.

MYELOID TUMOUR.

Mr. **Maurice Collis** said he had to show that evening some specimens illustrative of that class of disease which was known as myeloid or fibro-plastic tumours. Their favourite situation above all others was in the antrum. He had to present to the Society the specimens and casts of three of those tumours, and also a book of photographs containing, among others, the photograph of one of these patients. The first case he would only briefly allude to, as it had already been published. This patient came up to him in the latter end of June last, and was operated upon the 1st day of July. The cast was taken on the last day of June, and the second was taken on the 11th of July, ten days after the operation. On the same days the two photographs were taken, one before, the other after the operation. The rapidity with which this case healed was something quite out of the common. The other two cases he would briefly state from the notes of Mr. Sibthorpe. James Heffernan, a farmer, aged thirty, was admitted into hospital on January 20th, 1869. About ten months ago he was attacked with toothache, and lost one tooth on the right side of the face. He soon afterwards remarked a small lump beside his nose, which gave him no pain. It had been gradually increasing in size ever since. All the teeth on that side of the jaw became loose, but they were not carious. The tumour projected at the side of the nose, the projection on the cheek being about the size of a walnut, over which the skin was quite movable. The hard palate was not much interfered with as regards form, but as regards substance it was considerably softened, and pushed down a little. The nose was stuffed, but without pain. Mr. Collis punctured the tumour through its most prominent part, under the upper lip, and examined what came out of the grooved needle, and found that it consisted of the form of cell termed by Lébert fibro-plastic, and named by Mr. Paget myeloid. This form of growth is especially found in the antrum and medullary cavity of bones. He operated on the 22nd of January. The incision ran, not in the mesial line of the lip, which gives an unpleasant depression or tuck up in the lip afterwards, when the cicatrix reaches its maximum of contraction, but in the line which he always adopted now, at the side of the mesial line on one of the ridges prominent on everyone's upper lip. The upper lip was divided into three parts, a central part and two lateral ones, and at the place where the central joined the two lateral portions there was a line more or less prominent in every individual. If this line was followed in making the incision, it would be found that the cicatrix was much less marked. Whether in male or female, it would occupy a line or curve where there was naturally a mark, and where the contraction and mark would be less observed than on the mesial line where there was no mark. This improvement might seem but small, but it had already been adopted elsewhere, and at the Oxford meeting Mr. Paget alluded to it as a very marked improvement in the line of incision for performing this operation with the least amount of deformity. In this case the tumour projected more towards the palate, and towards the anterior wall of the antrum, and it was not necessary to do more than make an incision through the upper lip in this line, and dissect the softened covering of the tumour and off the palate with a common elevator such as they all had in their trephine cases. Having dissected off the soft covering towards the mesial line, he was enabled to insert a forceps and clip the bone away close to the mesial line, removing the whole row of teeth, but the mucous membrane had been peeled off the tumour there, and peeled off on the surface towards the mouth. By this means a sufficient amount of structure was preserved to keep the palate so far intact that the soft covering of the cheek and palate came into contact, and instead of there being an ugly hole, making the mouth and nose communicate, the cavity was separated by this septum. The upper attachments of the tumour were difficult to remove, and it was necessary to divide the tumour into two, which was easily done by the chain saw. The upper portion of the tumour, which went up close under the floor of the orbit, was picked out with the finger in bits. One of the characteristics of this tumour was that it would press aside the bony structures that came in its way, except those which were spongy, and these were absorbed more or less. The floor of the orbit was sometimes absorbed. The tumour was generally found to take one particular direction. Sometimes it grew upwards towards the eye, at another time downwards towards the palate; again, forwards towards the cheek or inwards towards the nose. By the operation which he performed the palate was preserved, and in adopting this course he was borne out by the latest publication at the other side of the water; Sir William Fergusson, in his recently published observations, spoke of those conservative operations in which the palate could be preserved, and the teeth and the floor of the orbit, and in which small and limited incisions were required for the removal of very considerable tumours. The soft covering of the palate was preserved, and the mucous membrane of the cheek, which had covered the extirpated portion of the tumour, was brought in contact by sutures, and joined to a considerable extent, a certain space being left open for the escape of matter. Instead of using wire sutures, Mr. Collis generally used horsehair, which had all the advantages of the wire without any of its disadvantages. The disadvantage of the metal suture in these delicate plastic operations was this, that although it would remain for months, if necessary, without producing irritation, except the first trifling irritation it excites like a seton, yet when it is being removed the little kinks of the wire, which could not be always perfectly got rid of, were apt to give pain, and to tear out, and he had seen nicely done plastic operations somewhat injured in this way. Two or three fibres of horsehair tied and twisted, and wetted in warm water when about to be used, would do quite as well as wire, would give little irritation, and could be cut off as easily as silk or thread. This patient got on well. On the 26th, four days after the operation, he got a smart attack of tonsillitis, which considerably alarmed those about him, but on making an incision into the tonsil the inflammation disappeared, and on the 11th of February, three weeks after the operation, he left the hospital with the cicatrix well united, very little marked, and with a palate very firm. Portions of the tumour were gelatinous and firm, and at the same time brittle. They were not like cancer, which was soft and pulpy, easily crushed up and reduced into a cream; whereas the portions of this tumour which he exhibited were somewhat tough, although brittle. The next case which he had to bring under their notice came in the day after the other, and was operated on three days after. The particulars were as follows. Esther McGhee, aged twenty-eight, from Ballycastle, in the county of Antrim, was admitted on the 21st of January. About a year ago she was attacked with toothache on the left side of the face. About a week afterwards she felt a small tumour about the size of a pea at the corner of the left nostril, which gradually increased in size until last March, when it was removed by Drs. Dunlop and O'Connor, of Ballycastle. She made a good recovery, but in May the tumour began to grow again. The incision which had been made was one of the old incisions straight down the lip outside the ala of the nose. The external projection of these tumours gave no idea of the amount of development they reached, so that although this tumour was described as being small externally it gave no idea of its exact size. However, the disease returned in two months, and it did not grow with any great rapidity until November. After that month it began to grow somewhat faster. It presented externally on the left side a tumour about the size of a walnut, projecting towards the malar bone and upwards towards the orbit, but not much forwards nor towards the nostril. The front teeth were all healthy; one or two of the molars were gone, but the hard palate was remarkably firm to the touch, except in one part. This case differed in the direction of growth from the one previously described, while the first case to which he had briefly alluded might be said to combine the two. In the third case the tumour passed upwards and outwards towards the malar bone, and forwards so as to destroy some of the front wall of the antrum. The incision required for the removal of it went but half way beside the nose, round the ala, and through the curved line of the lip. Finding that the bulk of the palate was sound, having dissected off the integument, which was firmly attached, and got to the upper part of the tumour, he divided the attachment of the malar bone to the tumour, and then with a strong forceps cut off the body of the tumour as close to the alveoli as he could go. Having got out the tumour in this way, he picked out with a gouge such portions of the hard palate as seemed to be implicated. In one spot only did the tumour go through the bony portion of the hard palate. A good deal of the tumour ran upwards into the sinuses of the upper portion of the antrum, pressing upwards to the floor of the orbit. This portion was easily removed with a finger behind the tumour, and he believed the finger would do a great deal of work in these cases. One could not only hook out a great portion of the tumour in this way, but could sometimes perceive where a portion of it was left behind. He had no doubt, as Sir William Fergusson had stated, that it was unnecessary to remove the entire of the maxillas as a rule. In this case, where after the first operation the disease returned in two months, they could not expect as favourable results as in other cases. In the case in which he had operated on the 11th of July there was a complete immunity from the return of the disease so far. He had heard of the patient last week, and she was wonderfully improved, and no sign of the disease returning. In the second case a very fair result might also be expected. In the third case, not only from the fact of the tumour returning, but from the rapidity with which it returned, and from the fleshy character of the secondary growth, the probable result would be a further return. Should it do so, he would not hesitate to remove the entire superior maxilla; but if they saw this patient with first-rate teeth, he thought they would agree with him that it was but right to give her a chance of retaining them by removing the tumour without removing all its bony surroundings. He thought it was most desirable to save the palate, and there were few cases in which the operation was justifiable, if they could not save at least its periosteum. He did not speak of cancer, which was rare in this situation, but in these myeloid tumours they generally found the soft covering of the palate safe from attack, and wherever it was free from disease it ought to be preserved. Mr. Collis concluded by saying that he had much pleasure in presenting to the museum of the College the casts of the tumours, and the book containing a collection of photographs of interesting cases of operation which had been under his care.

DISCUSSION.

Dr. **Mapother** said that from the experience he had had in St. Vincent's Hospital he thought the mode of operation adopted by Mr. Collis was a valuable improvement as regards the appearance of the patients afterwards; and it had another advantage, in enabling them to dispense with a second incision under the septum of the nose. If they made an incision along the edge of the filtrum, a still further incision would enter into the anterior naris. He had operated in this way, and seen his colleagues perform the operation in the same manner. In justice to the memory of the late Mr. O'Ferrall, it should be stated that he had performed this operation along the edge of the filtrum many years ago.

Professor **Hargrave** thought the Society ought to be indebted to Mr. Collis for the presentation of these very interesting photographs. In the early part of the present year he witnessed an operation performed by Mr. Wharton in the manner adopted by Mr. Collis, and the result was most satisfactory. He wished to ask Mr. Collis whether in the second case he had used the actual cautery. [Mr. Collis—I did.] He thought that in many of these operations about the face the actual cautery was not sufficiently employed. The late Mr. O'Beirne used the actual cautery at a white heat, and it was not painful. He had certainly witnessed it applied without pain to the patient. He did not approve of the gas cautery which had been introduced of late years. He thought it a dangerous double-edged sword, for he had seen surgeons and their assistants burning their fingers in using it.

Mr. **Croly** said that he thought the incision through the side of the filtrum was a matter which chiefly regarded the appearance of the patient. A point of far greater importance was, whether they ought to perform what the late Mr. Liston called grubbing operations in the upper jaw. These myeloid tumours, if he understood Mr. Paget rightly, were more likely to involve the bone itself and the periosteum than other structures. The only myeloid tumour in which he had the opportunity of operating did not involve the palate. He determined to remove the entire of the upper jaw, that being, in the opinion of his colleagues, the best course to adopt. On removing the jaw he found the tumour was closely adherent to the bones on every portion of the hard palate. He was quite sure that there were cases where the operation advocated by Mr. Collis was most useful, particularly cases of polypi. He thought the tumours of enchondromatous variety were more adapted for preserving the palate than those of a myeloid nature. Undoubtedly it was important to save the palate if it could be done with certainty of a successful result; but if they allowed any portion of the disease to remain, and it returned in eighteen months, the operation would not be found an improvement. He was an advocate, except in special cases, for taking out the entire of the upper jaw. The palate filled up in a wonderful manner in three months, and the deformity was not much.

Mr. **Wharton** said he had recently performed an operation exactly similar to that described by Mr. Collis, leaving the alveolar process, and with a satisfactory result. He should not like to bind himself to the opinion Mr. Croly laid down, that where no evidence of disease existed, the surgeon was justified in removing the palate. On the contrary, when there was no reason to think the palate was diseased it ought to be retained, and as soon as the disease returned it would be time enough to remove it. As to the nature of these tumours, although Mr. Paget said the myeloid tumour was not malignant, he gave two cases in which cancer occurred after the operation.

Mr. **Collis**, in reply, said it was of little moment whether Mr. O'Ferrall got credit for being the originator or not of the incision at the border of the filtrum. He could only say that it had not, so far as he was aware, been put on record before he brought it forward. The point of importance was, whether in practice it was found to be an improvement. In the second of these cases there was free bleeding from the artery, and the only means he had of stopping it was by the actual cautery, and when he had got the iron into his hand he passed it into every place where there was anything suspicious, particularly as this disease had returned after the original operation. He believed the gas cautery was valuable in some cases, but was not so efficient as the iron at a white heat. A new method had been introduced whereby the radiation of heat could be limited to a particular spot, namely, by laying collodion all round the place to which it was desired to limit the radiation from the white iron. As to Mr. Croly's observations, he thought that perhaps surgeons had not been sufficiently careful as to the appearance of their patients in these facial operations, and there might be something yet to learn as to the line of incision. As to grubbing operations, he was satisfied to put the opinion of Sir W. Fergusson against that of Liston; and he thought the opinion of the great leader of conservative surgery would stand equally with that of one who, however brilliant, was a slashing cutter. Mr. Paget said the myeloid tumour attacked the periosteum rather than the bone. He remembered a case of Mr. Quinlan's, in which there was a periosteal tumour not more than two lines in thickness, which expanded the antrum to a very large size, and required the removal of the superior maxilla, although the disease, as he had said, was strictly limited to two lines in thickness of the periosteum. He thought he might be satisfied with what Mr. Wharton had stated as a reply to the observations of Mr. Croly, namely, that if there was no evidence of the palate being affected, the surgeon would be doing wrong to remove it. It would be time enough when the disease returned to do so, and he believed Mr. Croly, in one of his first operations on the upper jaw, endeavoured to save the palate. As to the secondary growths he should say that no matter what difference there might be in the primary tumours, the secondary growths approached one another more closely. Whatever the disease might be primarily, schirrus, encephaloid, fibrous, myeloid, or simple strumous (and he had seen the most malignant growths occur after all these), the law was that in all those tumours having their origin in abnormal development of the healthy tissue of the body, especially the connective tissue, their secondary developments, however they might differ in their primary growths, approached one another, and it was natural they should do so. In our present state of knowledge they were not to expect much increase of pathological knowledge as to secondary growths. They must confine their attention to the primary growths. He had never met with a pathologist who could tell what was the primary growth of a secondary formation.

DUBLIN PATHOLOGICAL SOCIETY.

FEBRUARY 6, 1869.

ABDOMINAL ANEURISM.

Dr. MOORE said the morbid specimen he now exhibited was taken from the body of a man, aged 31, who had been admitted to Sir Patrick Dunn's Hospital on the 31st of December. About three years ago he was engaged in coaling the Cunard steam ships in Liverpool; he was paid according to the amount of work done, and had often worked continuously for twenty-four hours, during which time 120 or 130 tons of coal would be put into the ships. At this work he earned very good wages. On one occasion he fell a distance of twenty feet into the hold of one of the ships, and a short time afterwards he for the first time complained of pain in the back. He came over to Dublin and placed himself under the care of Mr. Tuffnell, and at that time he complained also of palpitation in the epigastrium. Under the care of Mr. Tuffnell he got rid of this palpitation and resumed his work, but after some time he was again obliged to return to Dublin, where he remained under Mr. Tuffnell for eight months. He then went back to Liverpool, and was for a time under the care of Dr. Waters. The pain in the back was the only thing of which he complained when he came into Sir P. Dunn's Hospital, but he was very pale, in fact a washed-out looking man. He had no dropsy of any kind; he complained of pain half-way between the ensiform cartilage and the umbilicus, which shot up under the left floating ribs. He passed his urine freely and naturally; it was of normal sp. gr., and contained no albumen. There was no jaundice; the pulsation was feeble in his iliac arteries, but there was no perceptible difference in them; there was visible pulsation in the radial arteries; his pulse was 84. On making a more careful examination, dulness was found over the precordial region, and a peculiar diastolic click, so to speak, but no bruit. Following the course of the great vessels, there was visible pulsation below the ensiform cartilage, where, on percussion, he was dull. On examining the same region, between the ensiform cartilage and the umbilicus with the stethoscope when in the recumbent position, a distinct bruit was audible; if put in an upright position, the bruit disappeared. On being turned on his face, he was clear along the spinal cord until the last dorsal vertebræ, where a well-marked bruit could be heard, particularly at the left of the spine, which became intensified until you came to the fourth lumbar vertebræ, a space of about four inches. When placed on his hands and knees, he did not lose the pulsation in front. Matters went on thus for some time, and the man became quite cheery. He had a cough, but this was relieved, and he got up and walked about the wards every day. On the day he died he was going about the ward as usual, when he called out suddenly, "Send for the doctor," but before the resident pupil could come to him he was dead. The *post-mortem* examination revealed general hypertrophy of the heart. There was frothy mucus in the larger tubes, and a rather congestive condition of the lungs, but nothing to account for immediate death. Coming down to the abdominal aorta, an aneurism was found which was as large as an orange. It was given off immediately at the cœliac axis; it had obliterated the right renal artery, and the right kidney was reduced to an ounce in weight, yet so far as his urinary organs seemed to be concerned he appeared to be perfectly healthy. The case was interesting in many points of view. Firstly, pathology had done a great deal to show them the differential diagnosis between this and many other diseases. If they contented themselves with examining the patient over the front of the abdomen they would perceive nothing which could not be accounted for by the existence of a tumour, a psoas, or a hepatic abscess. Therefore physical examination in front did not tell them a great deal; the indications to be observed in front were common to those tumours that pressed on the vessels, but if they placed the man on his hands and knees the tumour would fall forward and the bruit would disappear; the same thing would happen with a hepatic abscess, in the majority of which cases there would be a total absence of bruit when the man was placed on his hands and knees. In this case, owing to the persistency of the bruit in this position, they had no difficulty in diagnosing it as a case of aneurism. He might be asked was bruit along the spine exclusively pathognomonic of aneurism? It was not; but being confined to two or three inches along the spine (from the last dorsal to the fourth lumbar vertebræ), proved that it could not be due to aortic obstruction, which might produce a "bruit," *but which would have been continuous* from the nape of the neck downwards.

Dr. GRIMSHAW exhibited the brain and spinal cord of a patient who had died in Steevens's Hospital, under the care of Dr. Swan. The patient was a servant-girl, twenty-one years of age, and had been a fortnight ill before she was admitted to hospital on the 30th January. She had some nausea, headache, and general uneasiness, together with some slight cerebral symptoms. The only peculiarity about her was that she got up once or twice during the night, and walked about in consequence of great pain in the head. These attacks were sudden. Some days before admission to hospital she got diarrhœa and vomiting, the diarrhœa being of such a nature as to lead to a suspicion that she had typhoid fever. On admission to hospital she had vomiting and diarrhœa. The pain of the head of which she complained was very considerable. She had pains in the shoulders also, and in the back of the neck. In two days after admission (on the 2nd February) she had strabismus of both eyes. The pulse was 96, the temperature 101·2. During this day she became quite comatose; her hair was cut short and cold applied. Towards evening she got muttering delirium. Her pulse was then 120. He (Dr. Grimshaw) saw her on the following morning in consultation with Dr. Swan. He found her with a quick pulse, of a peculiar jerking character so frequently found in meningitis, the head drawn back, no stiffness of the limbs, quite insensible. The vomiting had been of the peculiar green colour seen in these cases. He came to the conclusion that the case was one of meningitis, although the symptoms were not well marked. There was a very slight retraction of the head, so slight that it was doubtful. The vomiting had ceased; the diarrhœa still continued. On the following day she was worse, and got another symptom of meningitis,—namely, hyperæsthesia, well marked, especially over the right hip and along the right thigh. On the 4th she was still worse, and died on the evening of the 5th. The temperature before death was 99·6; the pulse was imperceptible. She had not passed water during the two days preceding her death, except with the assistance of a catheter. No spots of any kind appeared on the body. The case was remarkable because of the slowness of the invasion of the disease. The *post-mortem* examination was made that day (6th February) by Dr. Grimshaw with the assistance of Dr. Bookey and Mr. Richard Swan; the rigor mortis was well marked. The whole of the body was covered with dark purple patches, none of which, as he had already said, appeared before death. On examining the brain and spinal cord, a large quantity of the usual dark fluid blood exuded from the larger vessels and sinuses; the cord presented a considerable amount of inflammation; there were many patches of lymphy effusion; it seemed to be rather firmer than usual; the upper part of the cord had not the symptoms so well marked as is often seen in such cases; the arachnoid over the base of the brain was opaque, and at one point a mass of greenish yellow deposit was present; the arachnoid at the upper surface of the cerebellum was opaque, and there was a considerable amount of deposit; the whole of the subarachnoid space was filled with fluid; there was a great deal of adhesion between the opposing hemispheres; the two anterior lobes of the brain were in contact, and adhesion had taken place between the opposed surfaces; and on looking at the falx cerebri, it was found to be very shallow, thus accounting for the surfaces being sufficiently in apposition to admit of adhesion.

Notice to Subscribers.—Subscriptions for the year ending Dec. 31st, 1868, are now due. Subscribers resident in England will greatly oblige by forwarding the usual amount, 22s. 6d., either by cheque or P.O.O., made payable to A. A. Tindall, 20 King William street, Strand, London.

Subscriptions in Ireland to be sent to 3 Lincoln place, Dublin, and in Scotland, to Maclachlan and Stewart, South Bridge, Edinburgh.

Advance subscriptions, 21s. 8d. post free per annum, for the current year, can also be paid as above.

REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR *is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price 5d. Stamped 6d.*

By Post to Annual Subscribers, £1 2 6
,, *If paid in advance,* 1 1 8

⁂ Post-Office Orders and Cheques to be drawn in favour of
A. A. TINDALL, 20, King William-street, Strand, London,
,, 3, Lincoln-place, Dublin,
MACLACHLAN & STEWART, South Bridge, Edinburgh.

WEDNESDAY, MARCH 10, 1869.

EDUCATIONAL REFORM.—No. XI.

THE abolition of excessive compulsion, a nearer approximation to uniformity, and perhaps some alteration for the better in the evidence of practical work in the wards, out-patient rooms, special departments, and post-mortem theatres of a hospital, demanded of the student, are about the highest achievements which can be expected of corporations left to their "own sweet will." Complete uniformity of requirement throughout the realm, in regard to medical studies, it would be idle to anticipate, without a considerable increase of external pressure; for the first duty of a corporation (towards itself) is to exist, and if one of the necessary conditions of the existence of any corporation happens to be to underbid another similar corporation, there will always be some corporations which frame their standards of attainments as they fix their fees—on the lowest working scale. The second duty of a corporation (towards itself) is to make a clear profit out of its mode of life—to "put money in its purse, honestly if it can, but, above all, to put money in its purse," and to have a handsome balance at the bank. If the fulfilment of these solemn duties happen to be antagonistic to amalgamation with another corporation for the purpose of granting an integral qualification to practise, why then, forsooth, the profession and the public must still submit to the injustice and the injury arising out of the existence of a number of medical men enjoying the privileges of registration and the *status* of fully qualified practitioners on the strength of fractional diplomas. Still will a College of Physicians be requiring less surgical practice than a College of Surgeons, a College of Surgeons less medical practice than a College of Physicians, and an Apothecaries' Hall no surgical practice at all. Still will one corporation ask for six months' dissections, another for twelve months', and a third for eighteen. Still will the number of midwifery cases to be attended vary from none to six, and from six to twenty. Still will examinations present every grade of efficiency, from culpable leniency and improper exemptions to fair and accurate tests of qualification to practise. The mild importunity of "recommendations" may produce a semblance of uniformity. Examinations may appear to be conducted practically and theoretically by written and *vivâ voce* answers; the papers of questions may be made to wear the aspect of searching severity; the numbers of hours and days devoted to the dreadful ordeals may appal the unprofessional observer, who knows none of "the secrets of the prison house," and yet, lo and behold! but "tell it not in Gath," nor whisper it upon the house-tops for very shame—teachers shall ever and anon be astonished at pupils whom they knew to be grossly deficient being dubbed "most accomplished men," altogether equal to undertaking the responsible duties of physicians and surgeons. The deed has been sometimes done at night, and a favourite instrument has been a "special examination. And so long as the Medical Council declines attempting to enforce uniformity, so long must some of the corporations continue to fulfil their natural instincts by spreading their nets to catch the largest number of fish. How cautiously—how tentatively—how delicately—must an English College of Surgeons proceed on the path of progress if it wishes to retain its thousands upon thousands of constituents! How nicely must a Scotch College adjust its fees to the means of applicants from the other side of the Tweed, so that, travelling expenses included, the whole cost of its diploma may not exceed that demanded for the rival diploma of a similar College in a different division of the Kingdom, and that the student, apprehensive or experienced of rejection in another place, may not be deterred from knocking for admittance at its hospitable, sympathetic, cosmopolitan gate! Uniformity of requirement and uniformity of examination are two different things. Both are really necessary, and both important, but a uniformity of good examinations is by far the more important of the two. Strongly, indeed, do we hold that there is, and must be, a certain course of study which every medical student must pass through before he can learn his profession, and that this necessary course it is the duty of examining corporations to discover, and render compulsory. Will anyone deny that a student cannot learn anatomy properly without dissection and actual inspection of the subject? Will anyone affirm that a student can become a practical physician without watching the progress of cases, and examining the organs after death? Can a man be said to be fit for practice who has never tested urine, and does not know the appearance of morbid products? Is *he* a thoroughly trained practitioner, who knows little or nothing of diseases of the eye, diseases of the ear, diseases of the skin, diseases of the mind—who cannot use the ophthalmoscope or laryngoscope, has never performed a surgical operation, and has never been taught the principles of public health, or undergone the practical training in the laboratory which would fit him to detect adulterated food and drink? If regulations insisting on the practical parts of the curriculum on dissection and study of the human body, on work in the chemical and physiological laboratories, on note-taking and observation of cases in the medical and surgical and obstetric wards under the superintendence of physicians and surgeons; on similar note-taking and observation of the blind, the deaf, the halt, and the insane; on the performance of a course of operations on the dead body;—if regulations such as these were universally adopted, then might attendance on set courses of lectures be flung to the winds as part of a compulsory code, and be left to the option of the student; and we would undertake to say that every lecturer really worth listening to, and teaching well, would have no cause to complain of deficiency of attendance. It is because real practical work has never been properly insisted on that lectures have been piled upon the student. No one denies that there are too many lectures; and no one admits that hygiene, pathology, diseases of women, and diseases of the eye, ear, skin, larynx, and mind, receive as much attention as is due to them. And why? Partly from the defective requirements of the Examining Bodies and partly from the impossibility of squeezing the subjects into a too crowded collection of existing lectures. A Chair of Public Health has been established at University College; but how, we should like to know, are the other schools to follow suit when they can neither provide the funds from the fees of students without increasing the general fee, or find a convenient time for the insertion of the course until the requirements of the examining boards are reduced to reason and order? Therapeutics are sadly neglected. Pathology stands on much the same footing. Has it ever received its due? Essential as a thorough knowledge of it is for making medicine a science, it has been ignored till recently in the corporate curricula. And even now nothing is needed beyond the signature of the pathologist to a certificate of bodily presence, and how angelic in its occurrences that bodily presence may be who does not know? Besides, the poor pathologist often receives no remuneration, because none can be spared from fees for existing courses, already, perhaps, inadequately recompensed. The general fee for medical education may not be sufficiently high, and it might fairly be increased if the authorities at the various schools could agree together to raise them simultaneously. But the chief fault lies with the examining boards and the Medical Council, in not demanding more thorough acquaintance with the practical subjects, and diminishing at least (if not abolishing) compulsory attendance on lectures.

But, strongly as we feel as to the necessity for uniformity of requirement, and the necessity for alteration and amendment in the amount and nature of present requirements, we would dispense with all kind of requirement, and be content with absolute freedom and free trade in education if we could obtain a uniformity of good effective examination. We are not of opinion that examinations, if properly conducted, are all sufficient; but if we had to choose between a multitude of outward observances, combined with imperfect and inefficient examinations, and stringent, honest examinations, without any observances at all, we should unhesitatingly choose the latter. We would willingly sacrifice all compulsion to thorough examinations if they could be obtained by the sacrifice. What, however, can we expect from a system which involves a rivalry of corporations, bidding for the students' patronage, and acquiring an amount of profit proportionate to the number of students who present themselves for examination? What can be expected from a corporation with a close constitution, self-elected examiners, and the bulk of its diplomates shut off from an effectual voice in the conduct of its affairs? To fight for improvement on the line of leaving such corporations, to effect improvements out of the abundance of their spontaneous good impulses, would be to ensure the most meagre results in the longest space of time. We are not insensible to what has been effected towards uniformity. Medicine has been added to the examination for the membership of the College of Surgeons, and Mr. Curling is to propose the addition of midwifery. The optional L. M. must be made compulsory, and cease as a separate diploma. But we cannot rest even here, nor can the councillor rest who uttered last year the following words:—"Think, gentlemen, what the Council of our College of Surgeons might have done in the last twenty-five years in promotion of medical science if it had administered its great trust disinterestedly. Admitting to the profession annually several hundred members (sometimes, I believe, as many as five hundred, besides Fellows), with a fee of £22 a head, and able, I presume, to allot fully half of this very large income to the payment of a proper examining board—what is the course which it has taken? It has treated the examinerships in its gift as mere lucrative perquisites of its own body, best to be divided among its own members, and with scarcely an exception, the ten oldest members of the Council have been the ten examiners of the College, sharing among them the payment I have described. The elder members of the Board have generally shown so much attachment to office that the succession of younger men has become more and more impeded, and of late, I believe, sixty years of age has been about the earliest time at which a man's turn could come to enter upon the functions and profit of an examiner at the College of Surgeons. Can you wonder, gentlemen, that medical education has languished in England when suffering under an influence like this? As regards the mere examination in surgery, it has been bad enough that men should be entering upon that duty at an age when, in a normal state of things, they would rather be preparing to abandon it; and I cannot but deem it to have been very mischievous even for practical surgery in this country that our examiners for long past years have been men from sixty to eighty years of age. But think, gentlemen, what the mischief must have been in relation to the sciences of our profession—that during this period of unexampled scientific progress, persons in the fourth and fifth vicenniads of life have been empowered to settle, according to their own dim lights, what should be the standard of scientific proficiency for men just entering the medical profession! And this state of things—*this utter corruption*—for *such it is*, has been defended by arguments which, if they mean anything mean that examinerships of vital importance to the strength and development of surgery and medicine may be used as *a kind of almshouse for effete members of our profession*. How different things might have been if some twenty-five years ago our councillors there, instead of resolving to stand in chronic antagonism to the scientific interests of our profession, had but exercised the same sort of self-denial as the senate of the University of London has exercised—had but resolved to disqualify themselves from appointing themselves or one another to be examiners—had allotted (say) two-thirds of their examination fund to the payment of separate examiners in the sciences, reserving one-third for surgical examiners, instead of jumbling all together, as at present—had put some decent limit of age even on their surgical examinerships, but specially as regards anatomy, physiology, and pathology, had gone on a quite new tack—had started with men then young enough to be their sons, but who were already eminent in scientific work, such men as Bowman, Paget, Bush, Quekett, Hewett, Birkett, Toynbee, Rainey, and others—and had from then till now taken care that all those parts of their examinations which grow with contemporary research should be in the hands of men fresh from the work-room,—how different, I say, would be the present state of things if, twenty-five years ago, that course had been begun! How different, I may add, will be the future state of things—how different, twenty years hence, the *status* of our London schools in the eye of European science, if even now, tardily, a course of that kind should be determined on!". We are anxiously awaiting the natural fruit of these vigorous words.

◆

SCOTLAND.

EDINBURGH.

MUSEUM OF SCIENCE AND ART.

Professor Turner delivered the first of a course of six lectures on "Elementary Anatomy and Physiology" in the hall of this museum on the 24th ult. He remarked, that in these lectures he could only give an outline of these twin sciences. He should therefore, he said, chiefly direct attention to the structure and functions of the human body, and stated the particular subjects which he should introduce into the different lectures as they were delivered. The one that night, which was listened to with attention, and frequently applauded, consisted principally of an explanation of the leading terms most commonly used in the two sciences.

PHILOSOPHICAL INSTITUTION.

A lecture on "School and College Education" was delivered on the 2nd inst. to the members of this Institution by Professor Jowett, of Oxford. He referred to the controversy which had been going on for the last three years between the friends and enemies of classical education. They might be termed, he said, the utilitarians and classicists—the friends of useful and of liberal education. He did not take either side. Scotland enjoyed the distinction of having continued the higher education in her parish schools; and whatever extension the system might be required, he hoped that this national characteristic of Scotch education would not be lost sight of, but that in any coming changes the ties between the parish schools and the Universities might be drawn still closer. What he meant by a liberal education was shown by the Professor, who then explained the method which should be pursued in the instruction of the young. Referring to the differences of religious opinion which exist, he said we hardly regard them in daily life, and we ought not to inflict hard words or terms of controversy upon those who come to be taught, but endeavour to impart principles which will survive all the changes which may take place in religious institutions.

UNIVERSITY.

The University Court have reappointed Sir William Gibson-Craig, Bart., Lord Clerk-Register, to be a Curator of Patronage of the University, and have appointed the Hon. Lord Neaves, LL.D., to be a Curator of Patronage, in succession to the Right Hon. the Lord Justice-General, whose term of office has expired. Both appointments are for three years.

HERIOT'S HOSPITAL.

This hospital made a claim of £40,000 for 21 acres of land taken by the North British Railway Company at Leith Walk, and the Company offered only £19,000. The case, in consequence of this discrepancy, came into Court, and, after a hearing of several days, £17,550 have been awarded to the hospital.

GLASGOW AND ABERDEEN.

On Wednesday last a number of the medical graduates of these Universities had an interview with Mr. Moncrieff, M.P., the Lord Advocate, in reference to subjects in which the medical profession was interested. Drs. Steward, Greenhow, Forbes Winslow, Bryson, Ramsay, and others were present. The principal point to which the deputation called the attention of his Lordship was the present state of the Medical Act. As it now stood, the Medical Council had no power to enforce its decision, and a wish was expressed that a penalty clause should be inserted in the Act, under which persons assuming medical titles without a diploma might be punished. Another suggestion was that the general body of practitioners should be represented upon the Medical Council; that the members of the Council should be elected by the whole body of the members, graduates, or fellows, as the case might be; and that Poor-law medical officers in Scotland, if dismissed by a local Board, should have the same power of appeal to the Central Board as is possessed by those officers in England. On the subject of registration of deaths, they complained of the inequality in which Scotch medical men were placed in being compelled, under penalty, to register deaths gratuitously. The deputation were specially desirous to invite his Lordship's assistance in obtaining the extension to Scotland of the Sanitary Commission. It was a matter of the highest importance to the public health. In reply, the Lord Advocate expressed the pleasure he felt in meeting his medical constituents in London. He concurred in several of the suggestions which had been made, and though not in favour of abolishing compulsory registration of deaths, he thought some remuneration should be allowed. He alluded to other particulars of their address, and expressed his willingness to forward their wishes as far as he could. The deputation then withdrew, after thanking the Lord Advocate for his courtesy. We hear that his Lordship will be entertained by his London constituents at a banquet at St. James's Hall on the 10th April. The Duke of Argyll will preside.

LEITH.

HOSPITAL.

From the report read at the annual meeting it appears that the funds of this hospital are in a depressed state, and that, in consequence, there had been a great diminution in the number of cases treated compared with the previous year. In the fever department the numbers had fallen from 189 to 81, and towards the end of the year this department was for a time entirely closed, not a single patient being under treatment for fever. It was the opinion of the meeting that an effort should be made to revive the interest in an institution so needful to the neighbourhood and so well deserving the support of all classes.

DRAINAGE.

A letter in the *Scotsman* of the 2nd inst. states that the owners of property in different parts of Leith are exposed to the influx of sewage waters into the cellars and lower floors of their dwelling-houses at certain times. Surely, on the ground of public health, the authorities are bound to take notice of this fact, and, if possible, remedy an evil which may at some future time give rise to the fearful consequences of an epidemic.

MONTROSE.

There was a large attendance at the monthly meeting of the Asylum Board at this place, Provost Mitchell presided. The report showed the number of patients in the house to be 163 men and 212 women; 13 had been removed to the Stirling district asylum. The value of the property possessed by this asylum is £34,036, and a sinking fund of £1,037. A letter was read from the representatives of John Black, Esq., Burnside of Keithock, bequeathing the sum of £130 to the Royal Infirmary.

HAWICK.

Mr. Blain called attention at the meeting of the Town Council to the smoke nuisance from the chimneys of the factories in town, and setting forth the great injury done thereby to the public generally, urged that steps should be taken to prosecute offenders. The Provost said the matter had been reported on to the Sanitary Committee by the Inspector of Nuisances, and he had been directed to make other observations and send in a second report. If they found the nuisance was continued they would then require to take the steps provided by law to put a stop to it.

PERTH.

GIRLS' HOUSE OF REFUGE AND REFORMATORY.

There was a large attendance at the annual meeting of this institution. The girls, fifty-five in number, who looked remarkably clean, healthful, and in good spirits, underwent an examination in reading, spelling, and Bible lessons, and made a most creditable appearance. Since the opening of the house 260 girls had been received, and since it had been licensed as a reformatory 65 had been taken in upon a magistrate's order. The girls who had gone to situations had generally given satisfaction to their employers. The funds are in a favourable state.

NICE.

(FROM OUR OWN CORRESPONDENT.)

Nice, March 1869.

THE WINTER ON THE CONTINENT.

I have noticed that much has been said lately about the mild winter. Here we have had but little skating, and on the whole the weather has not been decidedly severe, although eight or ten degrees of frost is certainly sharp. As a matter of health, I fear wind much more than frost; and after the gales that have played such havoc, we may expect yet more. Judging by my private letters, your winter in London has been much milder than ours. Frost and snow you have hardly tasted, but then you have had such a superabundance of rain that the excessive humidity must be very unfavourable. I have private letters, on which I can fully rely, from many parts of Europe, from which I gather that the winter has been very unequal; here severe, there mild, in another place changeable. Up to the end of the year 1868, it was almost universally mild, but the rainy days were more numerous. In Provence, the home of the old Troubadours, the little sunshiny corner of France, whither so many invalids repair, the winter has been very disappointing. Hyères, Cannes, Nice, and Mentone, and other parts, send reports of cloud, rain, and cold,—recently of frost even.

Between this capital and those towns there is now constant communication, and you may meet two or three times a week in the Clubs persons who have just returned or are just setting out for them. The former can, of course, compare this weather with that of the sunny South, and many of them speak of a condition that people are apt to forget may in any of these towns overtake them. The same may be said for the places on the Pyrenees; but beyond them few now venture on account of the unsettled state of Spain. Turn, then, to Italy, and a similar report reaches me. Florence has had a cold and changeable winter. Rome goes on in its old way, and, like Florence, grumbles at its paucity of visitors. Naples, the queen city of the Mediterranean, always changeable but always gay, has had a fit of cold such as she seldom has, and which, it is to be hoped, will destroy some of the pernicious effects of the filth that produces the only evil of that magnificent place. January, this year (though the early part seems to have been fine enough), brought a terrible frost and a violent snowstorm. I have often seen the top of Vesuvius covered with snow, while all below was summer sunshine. A letter tells me that this year the low grounds were all blanched; and a day or two ago I was talking to a family, who, reaching Naples about that time, immediately set out to return northwards —so piercing was the cold and so little expected. Had I been there I would have had more patience, sure that in a day or two no trace would remain save in the blighted lemons and almonds.

As you have a correspondent at Vienna he will give you, perhaps, a truthful statement. One letter told me that the people in December who went to the Splugen to bring in a supply of ice found only flowers—so mild was the winter. A later note received last week, telling me of the Prince of Wales's visit, describes some ice sports, and speaks of a temperature as low as 2° Fahr.

Notes on Current Topics.

Dr. Livingstone and the Paris Academy.

THE Academy of Sciences proceeded last week to the election of a Corresponding Member, in place of M. Dallas Buche, for the Section of Geography and Navigation. Three candidates were nominated: Dr. Livingstone for London, M. Cialdi for Rome, and Mr. Benjamin Gould for Washington. Out of 52 votes Dr. Livingstone received 48 suffrages, Mr. Gould 3, and M. Cialdi 1; and Dr. Livingstone was accordingly elected by an enormous majority.

The Trichina in Switzerland.

THE journals have announced recently the invasion of the Canton of Tessin by trichinosis. Six persons having died of it in one family, M. Paganini, a veterinary surgeon, investigated the fact. He submitted portions of human muscle and of pork to microscopic examination, and found both of them crowded with a multitude of the trichinæ.

Evolution of Carbonic Acid by Leaves.

M. BOUSSINGAULT has laid before the Academy of Sciences of Paris a continuation of his researches on this subject. The learned professor set himself to investigate whether, as Saussure believed, leaves continue to evolve carbonic acid in darkness. If a stick of phosphorus be plunged into an atmosphere of carbonic acid no reaction is produced. M. Boussingault has in his laboratory a flask in which these substances have been in contact for several years, and neither by day nor night is any effect apparent. But if, in another similar flask, a green leaf is introduced under the influence of light, thick vapours of hypophosphoric acid are at once formed. The leaf appropriates the carbon to itself, and the oxygen being evolved combines with the phosphorus. The same experiment repeated at night gives no result, nor is the least light visible on the phosphorus.

In diffused light, however feeble, the leaves act. M. Boussingault cites the effects which take place in tropical forests, in which the light penetrates with such difficulty that one cannot read at midday, yet the mosses and grass maintain a luxuriant verdure. Low temperatures are no obstacle to this influence of the leaves, for between zero and two degrees the carbonic acid is still evolved.

Professional Journalism on the Continent.

Two new journals are announced from the French press. The first is entitled the *Annals of Dermatology and Syphilography*, edited by Dr. Doyon, and will be the sole special representative of the literature of these diseases. The second is the *Photographic Review of the Parisian Hospitals*, which is published under the direction of Drs. Montmeja and Rengade. Two numbers have already been issued, and we can pronounce the photographic illustrations to be well executed and apparently truthful in detail.

Local Etherization in Strangulated Hernia.

Marseille Médicale publishes an interesting memoir on this subject from the pen of M. Chavernac, in which the author recapitulates all the existing means of reduction of strangulated intestine, which, he says, are not comparable in their efficiency to pulverized ether. He publishes many cases in support of his view.

Contagion of Consumption.

PROFESSOR CASTAN has enriched the pages of the *Montpelier Médicale* with a paper on this subject. He has collected together a variety of facts, which appear to show that tuberculosis may be communicated from a diseased to a healthy person by transpiration, breathed air, and living together.

A New Remedy in Erysipelas.

A NEW agent for the treatment of this disease has been brought to light by Professor Lücke, of Berne, who reports in a German periodical a large number of cases which show the salutary action of oil of turpentine in averting infectious and traumatic erysipelas. Prof. Schützenberger, of Strasburg, has investigated the truth of the statements, and he declares that the results obtained by him accord perfectly with those published by Professor Lücke. In four cases the disease had been very rapidly cured by turpentine inunctions, the local disease being checked and the temperature reduced from the third to the fifth day of the disease. In the cases thus treated the disease neither persisted nor extended from the moment of its invasion.

Tobacco Smoke in Intestinal Obstructions.

DR. OLIVE, of the Marseilles Dispensary, has had recourse successfully to tobacco smoke injections in the case of a man, thirty-eight years of age, who, despite injections of purgatives, oil, and tobacco, and of cold applications, was given over to certain death. With the help of a bellows M. Olive introduced the tobacco smoke into the intestine; the tympanitis appeared to increase, but after a short time three dark fœtid stools were passed, and the patient recovered at once.

Postpartum Retention of Urine.

M. MATTEI read last week a communication on this subject before the Paris Academy of Medicine, of which the conclusions are as follows:—

1. Retention is commonly attributed to two causes—swelling of the urethra in consequence of contusion, and vesical atony.

2. Catheterism in such cases indicates a cause as important as these alluded to.

3. During the last period of pregnancy, the bladder being drawn upwards along with the uterus, the urethral canal is necessarily elongated; so that, after delivery, the uterus descending brings the bladder with it, and the urethral canal is necessarily shortened by twisting and folding on itself.

4. It is difficult to obviate this accident; but the administration of one or two grammes of ergot after labour, by provoking retraction of the uterus, encourages also the vesical retraction, so as to render retention less frequent.

5. If catheterism be requisite on failure of this resource, the instrument should be left free to follow its own course through the temporary tortuosities of the urethra.

6. Catheterism, when necessary, readjusts the canal so perfectly that it is not required after one or two occasions. If it be found necessary to repeat it frequently it is evi-

dent that we have to deal, not with closure of the urethra, or contusions, or even vesical inertia, but rather with paralysis of the organ, which will require other treatment.

New French Books.

The following works have just issued from the Parisian press:—

Medical Climatology: its Basis and Organization. By Dr. Carrière. Price 2½ francs.

On Cutaneous Pigmentation in Cases of Phthisis. By Dr. Jeannin, of Lyons. With illustrations. Price 2 francs.

Medico-Chirurgical Clinique. By Prof. Piorry. 8vo, 536 pages. Price 6 francs.

Researches on the Umbilical Region, and on Hepatic Umbilical Fistulæ. By Dr. Lignerolles. Price 2½ francs.

The Responsibility of the Doctor before the Legal Tribunals. By Dr. Lelorrain. Price 1½ francs.

Dictionary of Pure and Applied Chemistry. By Dr. Wurtz. Fourth Fasciculus.

On Paralysis of the Common Oculo-Motor Nerve. By Dr. Cassoulet. Price 2½ francs.

The Theory of Vital Unity. By Dr. Galicier. Price 3½ francs.

Clinical Researches on the Modifications of Temperature and of the Pulse in Typhoid Fever and Small-pox. By Ernest Labbé. Illustrated with plates, sphygmographic tracings, and thermic curves. Price 3 francs.

Researches on Synostosis of the Cranial Bones, considered from the Normal and Pathological Points of View in the various Human Races. By Dr. Pommerol. With two lithographs. Price 2½ francs.

Remarks on the Theory of Progressive Locomotor Ataxy. By Dr. Uspensky. Price 75 centimes.

Female Doctors.

The *Feuille Médicale de St. Pétersbourg*, in noticing the invasion of the professional schools in that city by women, says that "since the nomination of Madame Kaschevarova to the doctorate of medicine, a crowd of women are occupied daily in the dead rooms of the Academy on the dissection of bodies. The occupation is certainly not likely to render the women engaged in it very attractive, and can hardly be considered conformable to the mission of the wife, whose whole energy ought to be concentrated in the bosom of their families. They desert their proper function and consecrate themselves to labours which necessarily estrange them from their domestic duties. To this consideration must be added the hindrances which the simultaneous concourse of pupils of both sexes interpose to serious scientific occupation."

The *Union Médicale* says:—"It is obvious that this promiscuity of the sexes in our schools must produce strange results. But the partizans of free trade in female medical studies may reply, 'Why not have special schools for women?' In fact, there are such in America; but truth obliges us to say that they are not very flourishing even in the country in which professional liberty is pushed to the degree of eccentricity."

Treatment of Somnambulism.

Professor Pellizari, of Florence, has published in the *Gazetta Medico Venetia* a new means of preventing and curing somnambulism, which, he says, he has used in eighteen cases with complete success. Every night, on going to bed, the somnambulist applies round his leg a few turns of thin copper wire, sufficiently long to communicate with the ground, and in the morning this conductor is removed. In one of the cases reported the conductor acted perfectly as a preventive, and in the others it had cured radically the somnambulism. The property possessed by the metal to dissipate promptly the magnetic somnambulism, and the rational hypothesis that this means can also cure spontaneous somnambulism, had induced the author to experiment by this method, which has yielded him very remarkable results.

The Relative Success of Military Surgery in England, France, and America.

M. Leon Lefort, Secretary of the Surgical Society of Paris, has published a series of papers in the *Gazette Hebdomadaire de Médecine*, on the relative excellence of army medical organizations in Great Britain, France, and America. M. Lefort reviews the results of surgery in the three armies, from which precise returns have been published. Laying aside the minor operations, he says that the French and British in the Crimea, and the American, so far as reported, have practised 12,291 of the major amputations thus:—

British Army	721
French „	4,703
American „ (Federal)	6,867

"Examining these operations in detail," he continues, "we discover the shocking inferiority of the French Medical Service. The ratios in the three armies are:—

	English Army. Mortal.	American Un. Army. Mortal.	French Army. Mortal.
Disarticulations at the shoulder	33·3	39·2	61·7
Amputations of the arm ...	24·5	21·2	55·5
Amputations of the forearm ...	5·0	16·5	45·2
Disarticulations at the hip ...	100·0	85·7	100·0
Amputations of the thigh ...	64·0	64·4	91·8
Disarticulations at the knee ...	57·1	55·1	91·3
Amputations of the leg ...	35·6	26·0	71·9
	40·2	33·9	72·8

"In thigh amputations, then, while the American and British lose 64 in 100, the French lose 91·8. The former lose but 26 per cent. in leg amputations, and we lose 71·9. Such a result is heartrending; it is essential to discuss the cause of such a state of things, for the welfare of French soldiers and the honour of French surgery demand imperiously that they be removed."

Royal Zoological and Geological Societies of Ireland.

It has been arranged to hold occasional joint meetings of these two Societies, for the purpose of reading papers of scientific interest. The first meeting will be held today (Wednesday), in the Museum Building of Trinity College, and the chair taken at a quarter past eight o'clock.

Zoological Papers.—1. Arthur W. Foot, M.D., "Remarks on the Fertility of some of the larger Carnivora in Confinement." 2. Sir Dominic J. Corrigan, Bart., M.D., "Observations on the Condition known as 'Roaring' in the Horse, and on the Pathology of this Disease.'

Geological Papers.—1. Mr. Alexander Dempster, "On the Prince of Wales' Gold Mine, at Ballarat, South Australia." 2. W. Lauder Lindsay, M.D., F.L.S., "On the Gold Fields of Scotland."

The Trade in Deformity.

The public appetite for monstrosities, which has attracted to London the Siamese Twins and the Nova Scotian Giantess, is, we assume, only another phase of the mania for hairbreadth temptations of Providence which brought the multitude of Blondins and Leotards into existence. It is a sentiment little creditable to the patrons of such exhibitions, and less so those of the press, who minister by the publication of disgusting details to such tastes.

All the world recollects the abominable picture of a case devoid of any scientific interest which appeared in the leading medical journal a year or two ago, and we have had in the daily press the offence repeated in a minor degree in the case of the Siamese Twins.

A few years ago a miserable boy suffering under the last and most repulsive degree of emaciation from disease was paraded in Dublin as "the living skeleton," and filthy traders on their affliction with hypospadias are constant visitors through the provinces. While money is to be earned by the exhibition of such abominations we presume it is futile to protest; but we have a right to look for better things from our literary censors than the public enumeration of all the details of such deformities.

The Medical Officers' Superannuation Bill (Ireland).

The draft of this Bill has been several times under the consideration of the Councils of the Royal College of Surgeons of Ireland and the Irish Medical Association, and has been finally approved by them. Mr. Pim, M.P. for Dublin City, Mr. Ion Trant Hamilton, the representative of the county, as representing respectively Liberalism and Conservatism, and Dr. Brady, M.P. for Leitrim, on the part of the profession, have notified their readiness to introduce the measure into the House of Commons and give it their best support.

It will be remembered that the opposition to Sir Colman O'Loghlen's Bill of last year was led by Mr. Gregory, who opposed it as a whole, but has pledged himself to support the Bill now about to be introduced. There is only one clause to which serious objection is apprehended—that which provides that in estimating the amount of the superannuation allowance the gross public remuneration, including the average vaccination and registration fees, shall be counted. We certainly fail to comprehend why, if it be considered just to grant retiring pensions for public services, the whole of those services should not be included.

A most vital consideration for the promoters of this measure is that the countenance, if not the official support, of the Irish Government should be, if possible, obtained. The Chief Secretary has already expressed himself favourably as regards the measure, and it is obvious that, to a great extent, the support or opposition of the Government is life or death to the Bill. In such a matter political considerations ought to be set aside, and we should earnestly counsel that the profession should, by an influential deputation, lay before the Government the manifold and weighty arguments of which there is no want.

American and Oriental Literature.

Messrs. Trubner's Monthly Register, which has just appeared, supplies us with a unique record of foreign literature not without its interest to medical men. A complete catalogue of American books issued within the month has its place in the Register, and in it will be found all the medical works which our readers will care to be informed about. The most valuable record, from a medical point of view, is the very useful catalogue of the contents of foreign medical periodicals in the English language, which, as far we know, is not to be found elsewhere. We regret our space will not permit us to furnish our readers with an index to the communications contained in this useful publication.

Army Medical Retrenchment.

The vote for hospital establishments, &c., shows a decrease of only £14,000. A large reduction has been made in the establishment of medical officers; but, as it is not intended to place on half-pay any of the junior officers who have recently passed by examination into the service, it has been found necessary to provide pay for those remaining supernumerary until absorbed. This, in a measure, accounts for this item not showing a decreased charge. The increase arises from the very large number of medical officers who during the year will become entitled to an increase of pay for length of service. The charge for subsistence of lunatics is decreasing; all officers are now handed over to their families at once, and the men are as rapidly as possible transferred either to the charge of their friends or of their parish.

The gross votes for the ensuing year relatively to those for 1868-69, are as follows:—

Medicines and medical stores.—To be voted for 1869-70, £79,300; last vote for 1868-69, £78,164; increase, £1,136. Expenditure in 1867-68, £87,736 5s. 2d.

Medical establishments at home and abroad.—To be voted for 1869-70, £54,757; last vote for 1868-69, £64,824; decrease, £10,067. Expenditure in 1867-68, £61,337 6s. 8d.

Iridectomy in Glaucoma.

The ophthalmic surgeons who have ridden the iridectomy hobby without being able to tell the world the why or the wherefore of their treatment, will be, no doubt, interested in learning the latest and most crushing argument in favour of this inexplicable procedure. Dr. Henry Noyes, of New York, has very recently communicated his views on glaucoma to the New York State Medical Society. He enumerates two causes of the disease—1, those referring to a diseased condition of the sclerotic, similar to arterial atheroma; and, 2, to irritation in some portion of the fifth pair of nerves. For the cure of a diseased condition of the sclerotic, or irritation in the trifacial nerve, the author simply echoes the iridectomy cry without attempting to show his hearers how the cutting out of a piece of the iris can restore the sclerotic to health, or remove irritation from the trifacial. He says—"The operation advised in all the curable stages was iridectomy, performed through the sclerotic, as near as possible to the point of the origin of the iris. The incision was recommended to be large enough to occupy from one-fifth to one-sixth of the circumference of the iris." But Mr Noyes at least merits thanks for plainly stating his own theory of the curative effect of iridectomy, and we make it a present to the advocates of this procedure. He thus expresses himself:—"The advantages of iridectomy were, in his opinion, due very greatly to the permanent relief to internal pressure by the substitution of an elastic cica trix in the place where it is most needed." Is it not the legitimate deduction from all this that ophthalmic surgeons are advised to excise a portion of the iris in order to make an elastic cicatrix for the cure of disease of the sclerotic or trifacial irritation—or is it not rather the *sequitur* that neither Dr. Noyes or any other of the iridectomists know anything whatever about the physiological action (if there be any) of this operation, and are simply acting on unsupported theories and *ex parte* records of results ?

The Typhoid Fever at Brussels.

The epidemic has at last commenced its decline, the patients being less numerous, and those who are attacked suffering from less severe symptoms. In order to permit the students and professors to devote themselves completely to the care of the sufferers, the course of study at the medical schools has been suspended, and for fear of the contagion the pupils of the military schools and most of the collegians have been sent to their homes.

An extraordinary circumstance is the tardiness of the convalescence. The patients recover only very slowly, and the greatest care has to be exercised in regard to their nourishment. The least mistake in their dietary provokes indigestion of greater or less severity, or re-establishes a febrile excitement which is not easily got rid of.

Irish Lunatic Asylums.

We observe with great satisfaction that the Irish lunatic asylum system is likely to receive the attention and reform which its demerits deserve. The readers of the Medical Press and Circular have been at the time when they were enacted made familiar with all the details of the Privy Council rules under which the asylums are now administered. By these regulations the entire control of the institutions, and the government of the Boards of Governors and of the visiting physicians, were practically confided to the resident medical superintendents, subject only to the voice of the Lord-Lieutenant, whose utterances, as everyone knows, are never called forth but by a password from the back stairs of Dublin Castle. The system has worked notoriously, and the abuses which always result from irresponsible command have made themselves public. In the case of lunatics, more than in any other public service, is jealous *surveillance* called for, and we earnestly trust that in any future arrangements that supervision on the part of the governors and the visiting physicians will not be abrogated as it is at present.

Turpentine as an Antidote to Phosphorus.

M. Personne, *Pharmacien* to the Hospital of La Pitie, communicated last week to the Paris Academy of Medicine his researches on this subject. He had instituted three series of experiments on dogs.

In the first series he administered phosphorus alone to various animals, who all died at the end of a variable period.

In the second he administered the phosphorus, and followed it, some hours afterwards, with essence of turpentine, and the animals in this case experienced symptoms of poisoning, but none of them died.

To the third series of animals he administered essence of turpentine immediately after the phosphorus, and none of them suffered from a greater inconvenience than a slight indisposition.

According to the author, the explanation of these facts depends on the property possessed by essence of turpentine of preventing the burning of the phosphorus, which depends on its exposure to oxygen either in the air or the animal economy.

Hospital for Seamen.

We quote the following appeal for an hospital which has been made at Holyhead by the Queen's Harbour-master : "The want of an hospital is most severely felt at Holyhead, to receive seamen from the shipping. They are frequently landed having infectious diseases, and also disabled from accidents, such as falling from aloft. There is not at present any such asylum in existence. Cases of death have occurred in town from fever brought in by shipping and spreading among the population. The Board of Trade have kindly consented to give a Government site for building, if sufficient funds can be raised for the purpose. For months in the winter season we have from two to three hundred ships and vessels of all nations in port, taking refuge from gales of wind, varying in tonnage from the Great Eastern to the smallest coasting trader ; therefore our requirement is not only local, but a general and national one, and more especially as our anchorage is in the stream of trade to and from both Liverpool and Glasgow."

Death through Mistake.

The Governors of Worcester Infirmary lately appointed a committee to enquire into the facts connected with the death of an inmate of the institution from an improper administration of carbolic acid prescribed for another patient. From the investigation, it appeared that the medical attendant dictated the prescription at the bedside of the patient to the house-surgeon, who made it up and applied it himself. Next day the dispenser, who had read the prescription, prepared it from memory, and put the wrong name on the label, which was the cause of the accident. Where the blame lay it is almost impossible to tell from the account as it appears in the *Times*. The committee attribute it to the gross negligence and misconduct of the dispenser, and consider that he ought to be prosecuted. They probably had reasons which justified their decision, and the resignation and disappearance of the dispenser seem to corroborate it.

Amenities of Poor-law Medical Officers.

At Ulverston, last week, several serious charges were preferred against the master and matron of the workhouse by Mr. R. Cranke, the medical officer to the parish. The charges were, interference with the duties of the medical officer, particularly in the case of a fever patient, who was dismissed by them from the fever ward and sent down to the body of the house without the concurrence of Mr. Cranke, and while she was in a state both dangerous to her own health and that of the other inmates ; and further, that when the master was requested to have her removed back to the ward, he obstinately refused. The next charge was that of the master's neglect of duty in not attending to the dietary of the inmates of the house, they not having a sufficient quantity of food, and not according to the published dietary.

There were several other charges of insubordination and immoral conduct which were gone into by the Poor-law Inspectors, who will make a report to the Poor-law Board upon the inquiry, which lasted nearly three days. The charges appear *primâ facie* to be established; but, pending the publication of the official report, it would be injudicious to pass judgment upon the case.

M. Warlomont, of Brussels, has been appointed oculist to Her Majesty the Queen of the Belgians.

At the Royal Institution, on Thursday, at three o'clock, Dr. H. Power will lecture on the eye; on Friday, at eight o'clock, Dr. Crum Brown on chemical constitution; and on Saturday, at three o'clock, Dr. Odling on hydrogen.

The number of surgeons doing duty in Chatham Dockyard is to be reduced, and the appointment of assistant-surgeon is to be abolished. It is held at present by Dr. Moore. The stipend is £400 a year, with a residence in the yard.

The magistrates of Cheltenham have granted a new trial in the now famous case, "Hodson *v.* Harrison," the chief ground being the absence, during the last trial, of the most material witness, Dr. Rumsey, of Cheltenham.

It is stated that seven cases of illness caused by eating pork affected with *trichina spiralis* have occurred in New York city, two of them proving fatal. This re-appearance of the dreaded disease has caused some alarm.

The Committee of the German Hospital have signified their intention of holding a bazaar at the Queen's Concert rooms, Hanover square, on the 2nd June and two following days, under the patronage of Her Majesty the Queen. Their object in so doing is to raise funds for liquidating the debt on the new building, which is still as much as £2,000, and, should their efforts be rewarded with a sufficient amount of success, they intend opening the last unoccupied ward, which contains 25 beds.

A meeting was held at the house of Mr. Mitford, M.P., in Cavendish square, of gentlemen connected with the Association formed for extending the operation of the Contagious Diseases Act to the civil population. Mr. Berkley Hill and Mr. Curgenven read reports, showing that many other noblemen and gentlemen had given their names in support of this Association. Mr. Mitford, Mr. E. Hart, and others, urged the necessity of pressing upon the Government the adoption of stringent preventive measures, but it was agreed to wait until the Government measure should be introduced.

The mean of the Quarterly Returns of the Registrar-General for 1868, shows a remarkable variation in the death-rate of the several towns. Cheltenham and Devonport show the same rate of mortality, viz., 17·35 per 1,000, while the mortality in Manchester amounted to 32·01 per 1,000, so that in the latter place people have died nearly twice as fast as in the two former. Surely this calls for investigation. It behoves the inhabitants of Manchester at least to awake to their own interest, and see whether such a state of things is inevitable.

Mr. Solly took the chair at the annual meeting of the Royal Medical and Chirurgical Society. The business related to the pecuniary interests of the Society, the manner in which the funds had been appropriated showing an excess of income over expenditure. It was proposed to lower the fee. Mr. Solly expressed his desire that the name of the Society should be changed to that of "the Royal Society of Medicine and Surgery," or "the Royal Academy of Medicine;" that the other Societies of London should be united with it, and a building should be obtained worthy of the profession.

It has been affirmed and strongly insisted on, that ironclad vessels must necessarily be prejudicial to the health of their crews; but it has been found that such is by no means the case. In the official report on the health of the navy there is a table of the ratio of cases of disease and injury under treatment during twelve months, in various classes of vessels now serving abroad; and Dr. Mackay, in his introductory observations to the statistics, says: "This table shows the ironclad vessels in a very favourable light, the ratio of cases in them being considerably lower than in any of the rated vessels, and lower than in the sloops, gun-vessels, and gun-boats."

Correspondence.

REPRESSION OF QUACKERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am exceedingly glad to note the proposal contained in your leading article of yesterday's date. The misery and ruin produced by the artful system pursued by the advertising quacks is incalculable. I have had opportunities of a special kind for obtaining some glimpses of it, and might exclaim with Hamlet, "Horrible, most horrible!"

The suggestion that the repression of this kind of quackery should be taken up as a philanthropic movement is also most useful, and I should be glad to join publicly or privately in such a movement, to establish an association by any aid which tongue or pen can give. My offices are at the disposal of any gentlemen who are willing to co-operate in such a movement, as a centre to which correspondence may be addressed, or for preliminary committee meetings.

Action cannot be taken too soon, and half-a-dozen really earnest men would form a nucleus round which the outside public would readily aggregate. I am confident that a great success could be secured if a preliminary committee were formed, and a public appeal issued.

The mode in which you propose to make the attack upon these cruel scoundrels is by depriving them of their profits and starving them out by protecting their victims. This is sound policy, and I know that is practicable because I can quote cases. If any sensible, firm, and conscientious man can once get between the quack and his prey—the quack can be made to disgorge.

I am, dear Sir,
Yours faithfully,
J. Baxter Langley.

50, Lincoln's Inn Fields, W.C.
March 4th, 1869.

"A CANARD," OR "A FEELER."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It is stated in an annotation in the *Lancet* of Feb. 20, that "a well-known practitioner of cutaneous medicine and

surgery" has made a proposition to the Council of the Royal College of Surgeons of England to give £5,000 to found a professorship of "dermatology;" such gift to be accompanied by certain wax-works, and contingent upon the donor's appointment as the first "Professor." Who is this *fully qualified* gentleman whose reputation requires official recognition, and who *is said* to have insulted the College by an offer to purchase a professorship? The profession would, I think, like to know, and I, personally, as one of the very few doubly-qualified practitioners in this branch of medicine, desire to repudiate any knowledge of the matter.

Yours faithfully,

Dover street, W., March 1, 1869. Barr Meadows.

Gleanings in Medicine, Surgery, and the Allied Sciences.

MEDICINE.

TREATMENT OF BILIOUS REMITTENT FEVER.

Dr. W. B. Harvey, of Canton, Miss., in a communication to the *New Orleans Journal of Medicine*, relates the following easy and rapid mode of subduing this very serious affection. It is to be hoped that others who adopt the practice may have results equally satisfactory: "Regardless of the stage, grade, or duration of the fever, the patient is directed to take a half gr. sulph. morphia, incorporated with gr. xv of blue mass, to be followed, in half an hour, by grs. x of sulph. of quinine (in pills) and at the same time a warm foot bath, the vessel to be placed in the bed and the feet kept in it for half an hour. The dose of quinine to be repeated in two hours. This, together with a little castor oil, in ten hours, to prevent ptyalism, is the sum of treatment, and the result, in my hands, has been a profuse perspiration and a speedy subsidence of all the symptoms—pain in the head and back, thirst, &c., &c. The fever may be expected to be subdued in four or six hours. While all must regard such success as a great desideratum, many, I am persuaded, will receive my suggestion with distrust, and few, I apprehend, will have the boldness to subject it to a practical test."

SURGERY.

SYPHILIS CONTRACTED FROM CIGAR STUMPS:

Mons. Ambrosoli reports in the *Giornale Italiao della Malattie Nerncrée*, two cases of syphilis contracted by chewing the stumps of cigars picked up in the street. The primary lesion was seated, in one case, upon the anterior pillar of the soft palate, in the second case upon the palatine arch.—*N. Y. Med. Journ.*

SNARE FOR REMOVING FOREIGN BODIES FROM THE URETHRA.

Dr. J. T. Hodgen, professor of anatomy in St. Louis Medical College, describes (*St. Louis Med. Journ.*, Nov. 10, 1868) a very ingenious instrument for this purpose. He was called to a child suffering from retention of urine, and passing a catheter about two inches into the urethra it came in contact with a calculus. Not being provided with the usual instruments for removing such an obstruction, it occurred to him that by bending the wire found in his silver catheter (used to clear the instrument) he could form a loop that would readily pass the stone and encircle it, and that the stone might be withdrawn as corks are removed from bottles. He immediately put this idea into practice and drew out the calculus. He was subsequently called to a similar case, in which he resorted to the same expedient with like success. He has since had an instrument made on this principle, with two wires forming a double loop, which will no doubt prove useful.

◆

Medico-Parliamentary Intelligence.

HOUSE OF COMMONS—Thursday.

GILBERT UNIONS.

Mr. Mitford asked the President of the Poor-law Board, if the Poor-law Board intended to exercise their powers with respect to the dissolution of Gilbert unions during the present year.

Mr. Goschen replied that it was the intention of the Board to exercise its power in respect to the dissolution of such unions.

FEVER HOSPITAL PATIENTS.

Captain Dawson-Damer asked the President of the Poor-law Board, whether it was the case that three or four patients, recently brought to the Fever Hospital from different workhouses, were found dead on arrival there, in consequence of having been conveyed in a sitting posture in cabs, instead of being conveyed in proper ambulances; and whether each parish should not be bound to provide a fever ambulance.

Mr. Goschen said it was unfortunately but too true that such an occurrence had taken place, and though it was impossible to say that the patients had really died in consequence of their being conveyed in a sitting posture, yet the medical gentlemen were of opinion that that might have contributed to the fatal result. With regard to the second part of the question, he had to say that the parishes were not bound to provide ambulances. The matter, however, was under the consideration of the Poor-law Board, who would propose that the Metropolitan Asylum Board should provide proper carriages for the purpose.

PAUPER EMIGRATION TO THE UNITED STATES.

Sir T. Lloyd asked the President of the Poor-law Board whether he was prepared to take into consideration the propriety of relaxing the rule now in force by which the Poor-law Board refused its sanction to grants of money from boards of guardians in aid of paupers desirous of emigrating to the United States of America, and limited such sanction only to intending emigrants to our British colonial possessions.

Mr. Goschen replied that since he himself had been at the Poor-law Board the subject had been taken into consideration with a view to some relaxation of the rules. It was not at present the law to grant aid to paupers desirous of emigrating to the United States, because a great many years ago the American Government objected to pauper emigrants being sent to their country. He trusted, however, that the Poor-law Board would soon be able to get some of the restrictions removed, and that emigration might be promoted.

CONTAGIOUS DISEASES AMONG CATTLE.

Mr. W. E. Forster moved that leave be given to bring in a Bill to consolidate, amend, and make perpetual the Acts for preventing the introduction or spreading of contagious or infectious diseases among cattle and other animals in Great Britain. It was proposed, he said, to re-enact almost precisely as they stood the present regulations for stamping out the cattle plague should it unfortunately break out again, for giving the power of declaring certain places infected, for inspection, for preventing the removal of animals, and for compulsory slaughter. They proposed to take powers to check other diseases than cattle plague and sheep-pox; in fact, they proposed to take power to check lung disease and foot-and-mouth disease—any contagious disease, in short, among sheep, cattle, or horses.

Lord R. Montagu congratulated the right hon. gentleman on the manner in which he had approached the subject, and expressed the pleasure he felt at hearing that the Government, not regarding the matter as a party one, were willing to receive suggestions from whatever quarter they might be offered.

Several other members addressed the House, and Mr. Forster replied. Leave was given to bring in the Bill, which was subsequently introduced and read a first time.

PHARMACY ACT (1868) AMENDMENT BILL.

In committee of the whole House,

Lord R. Montagu moved that the chairman be directed to move the House that leave be given to bring in a bill to amend the Pharmacy Act, 1868. He said the Bill consisted of only one clause. In England medical practitioners, who were generally licensed apothecaries also, and veterinary surgeons, were able to take medicines with them and to dispense them, but in Scotland neither of those classes of professional men were able to dispense medicines, as there was no licensing power in Scotland to enable them to do so. It was a matter of serious consequence that this state of things should be altered, for it might happen that a doctor might be attending a patient some twenty miles away from the nearest druggist's shop. This Bill was to make the necessary change in the Act of last year.

Dr. **Brewer** said he feared that the action of the bill would be of a retrograde character.

After a few words in explanation from Lord R. Montagu, the House resumed, and leave was given to bring in the Bill.

◆

Medical News.

Apothecaries' Hall.—At a Court of Examiners, held on the 4th inst., the following gentlemen, having passed the necessary examinations, were admitted licentiates of the Society of Apothecaries, viz. :—Messrs. Thomas Allen, of Whitby; Andreas G. H. Bösenberg, of the Cape of Good Hope; George Henry, of Kingstown, Dublin; Alfred Armitage Kidger, of Ashby-de-la-Zouch; William Howell Lloyd, of Llangathen; George Thompson, of Wakefield; and Thomas Warren, of Princes Risborough.

By the will of the late John Bairstow, Esq., of Preston, the Infirmary of that town receives the munificent bequest of £19,500, which is to be devoted to the erection of a new wing to the existing building. The Royal Asylum for Idiots at Lancaster also receives £5,000 by the will of the same testator; the Medical Benevolent College, £300; the Medical Benevolent Fund, £300, besides several very liberal bequests to other institutions.

Presentations to Her Majesty.—At the levée holden on Friday last by the Queen at Buckingham Palace, the following members of the profession had the honour of being presented to Her Majesty :—Mr. Oscar Clayton, on appointment as extra-Surgeon in Ordinary to H.R.H. the Prince of Wales, and Surgeon to H.R.H. the Duke of Edinburgh; Dr. S. Currie, Inspector-General of Hospitals; Dr. R. W. Cunningham, Bengal Medical Service; Dr. John L. Erskine, Royal Engineers; Dr. W. Geoghegan, on his appointment as Staff-Surgeon; Surgeon-Major J. Hilliard, M.D.; Mr. Ross Jameson, Inspector-General of Hospitals; Mr. Jonas R. Leake; Assistant-Surgeon Bonney, Royal Surrey Militia; Surgeon-Major John Madden, M.D.; Surgeon-Major M. F. Manifold; Mr. J. T. Milburn; Mr. G. Munday; Mr. W. H. Pollard; Mr. W. H. Rendell; Mr. S. Robertson, Staff-Surgeon; Dr. W. Sedgwick Saunders, on appointment as Commissioner of the City of London; Dr. A. Simpson; Surgeon-Major L. Sinclair, M.D., on promotion and return from Abyssinia; Staff-Assistant-Surgeon Count Cyprian Wollowicz, &c. The majority of these presentations were made by the Director-General of the Army Medical Department.

A meeting took place on Friday evening at the rooms of the Society of Arts, under the presidency of the Earl of Ducie, having for its objects :—To better the condition of farm labourers by the removal, at proper seasons, of surplus labour from over-populated districts to places where labour is in greater demand; to encourage the more extensive building and improvement of cottages in accordance with the demands of health, decency, and comfort; to encourage elementary and technical education of the children of agricultural labourers; to promote sanitary reforms in villages, small communities, and dwellings of agricultural labourers; the separation of labourers' provident societies from public-houses, and their establishment on safe and economical principles and under proper management, so as to secure to those able and willing to save some means of support in times of sickness and disablement from work. The meeting was well attended, and was addressed by several noblemen and gentlemen. All the speakers acknowledged the deplorable condition the agricultural labourers were in; but as many of the subjects which would be embraced in the proposed society were already partially met by numerous societies now in existence, it was unanimously resolved, on the motion of Mr. Holland, seconded by Mr. W. Wells, "That this meeting considers it inexpedient to call into existence such a society as proposed." A vote of thanks to the noble chairman terminated the proceedings.

◆

NOTICES TO CORRESPONDENTS.

Mr. Walter Bernard.—Your note on "The Reunion of Joints," shall appear in our next.

Mr. Harry Stapleton,—"On Medullary Cancer" received. Proof shall be sent you as requested.

"Obstetric Memoranda," by Dr. Waring-Curran, Manchester. See previous reply.

Veritas.—The letter may be in bad taste, but we cannot disregard its argument on the ground of personal merit.

Dr. Cockcroft Keighley is thanked.

Army Assistant-Surgeon.—There have been a few appointments to H.M. Indian Medical Service, which you will find in another column.

Dr. Evory Kennedy "On Puerperal Fever. If possible in our next.

D. O. D., Rawlings' Hotel.—Thanks. The Journal shall be sent to Millview, as desired.

Enquirer.—We believe Dr. Hunter of Inhalation Notoriety, left for America soon after the trial of "Hunter v. Sharpe"—With him also his gigantic advertisements, disappeared from the daily papers.—Neither have since been seen or heard of in England.

Communications, enclosures, &c., received from Mr. F. Cooke, Ashton; Dr. Morris, Deddington; Mr. C. Spurgin, Colchester; Mr. Andrew Lewis, Carlisle; Mr. W. S. Whatford, Brighton; Mr. Curgenven, London; Mr. Handford, Mr. Holmes Coote, Dr. Edwards Crisp, Chelsea, Mr. W. B. Woodman, Limehouse; Dr. Agar, Ponders end; Dr. Cotter, Jamaica; Mr. John Messent; Mr. Palmer, Dr. Whittington, Tuxford; Mr. W. Cadge, Norwich; Mr. Burnett, Hull; Mr. Samson Gamgee, Birmingham; Mr. May, Mr. Hutchinson, Cheadle; Mr. Erichsen, London; Surgeon N. Alcock, 85th Regiment; Mr. Thomas Falcon, Leeds; Mr. Henry Sandham, Dr. Barr Meadows; Mr. R. Brown, Manchester; Dr. Barton, Dr. Fixot, St. Heliers; Mr. J. Baxter Langley, Mr. Barker, Dr. Bankien, Glasgow; Dr. Barry,. Dr. Deacon, Tenby; Dr. J. Blake, Taunton; Mr. J. C. Sargeant, Mr. G. Chater, Tenby; Dr. J. Cockcroft, Keighley; Dr. Robertson, London; Dr. Thorowgood, London; Dr. J. Wyatt Crane, Leicester; Dr. Peirson, Scarborough; Dr. Cranke, Ulverstone; Dr. Hawkins, London; Mr. F. Bentley, Manchester; Dr. Donovan, London; Dr. William Harrison, Leeds; Mr. Richards, Weobley; Dr. Collard, Sunderland; Dr. Spottiswood, Cahirciveen; Dr. Crawford, Tandragee; Dr. O'Kelly. Maynooth; Dr. Goodison, Enniscorthy; Dr. Lever, Frankford; Dr. Morton, Castleblayney; Dr. Sproule, Moville; Dr. Coates, Portumma; Dr. Beamish, Passagewest; Dr. Harvey, Cork; Dr. Hughes, Oranmore; Dr. Buckmaster, Middleton; Dr. Griffin, Kilkee; Dr. McBride, Newry; Dr. Haines, Midleton; Dr. Webb, Cashel; Dr. Deverell, Ardglass; Dr. Welsh, Ballyshannon; Dr. Carry, Belfast; Dr. Fitzpatrick, Enniskillen; Dr. Luther, Cappoquin; Dr. Toole, Bandon; Dr. Harpur, Killyleigh; Mr. Tichborne, Dublin; Dr. Evory Kennedy, Dublin, &c., &c.

CARBOLIC ACID IN SMALL-POX.

Arthur B. Stout, M.D. (*California Med. Gazette*), has great confidence in *carbolic acid* in mitigating small-pox, and divesting it of its *contagious* character. He believes that its course may be shortened, and by this agent the poison will be destroyed, be it animal or vegetable in its nature. Carbolic acid not only extinguishes the existing germs, but arrests their future development in the fluids in which it is infused. In conjunction with the use of the *Sarracenia purpurea*, he is confident that the general horror and fear and desertion from the holiest duties of life, which follow the announcement of small-pox may be put at an end. Let the patient be lightly moistened over several times daily with a weak solution of carbolic (phrenic) acid. Use a broad camel's hair brush, say two inches wide. The cure of the pustules will be hastened, it being a gentle stimulant. After its first use, and the slight infusion of its vapour in the air, giving to the atmosphere a faint odour like creosote, and plunging all the cast off clothing into a solution of this acid, the patient and the apartment occupied will be disinfected. The inhalation of carbolic acid vapour, as it comes atomized from a weak solution in Cologne water, commences the internal carbolization of the system. Carbolic acid should be given internally, so as to eradicate the poison in the tissues; the dose being from one half to one drop of the alcoholic solution and may be given with the sarracenia. The *Sarracenia purpurea* was introduced into the profession in 1861, by Dr. F. W. Morris, of Halifax, Nova Scotia. Keith & Co. prepare the extract, which he uses in doses of a teaspoonful every two hours.

MORPHIA IN ANÆSTHESIA.

Prof. Green, of the Marine Medical School (*Missouri Dental Journal*), recommends morphia as an antidote to nausea, during and after the anæsthetic state, and also to the other unpleasant after effects of an anæsthetic. It is to be given at the commencement of anæsthesia.

CHLOROSIS A DISEASE OF THE NERVOUS SYSTEM.

DR. WM. A. HAMMOND maintains (*Quart. Journ. Psycholog. Med.*) that chlorosis is primarily and essentially a disease of the nervous system, and that the changes which sometimes—by no means invariably—take place in the composition of the blood, are consequences of the nervous disorders and not its causes. "I do not contend," he says, "for the invariable occurrence of chlorosis without depravation of the blood. I insist, however, upon the point that chlorosis is a disease of the nervous system, and that when morbid changes take place in the blood during its continuance, they are always secondary and directly the consequences of the nervous derangement, and that therefore they are nothing more than accompaniments of the chlorotic condition ; also that frequently chlorosis runs its course without any of the symptoms of pathological changes in the blood being manifested. In the enunciation of this opinion I claim nothing on the score of originality. . . . I merely wish to present the view more connectedly and prominently than has yet been done."

Advertisements.

NOTICE TO ADVERTISERS.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a mos valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under..............	£0	3s.	6d.
Per line afterwards..............	0	0s.	6d.
One-quarter page..............	1	5s.	0d.
Half ,, ...	2	5s.	0d.
One ,, ...	4	0s.	0d.

The average of words per line is twelve.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

THE NOVA SCOTIA GIANTESS, MISS ANNA SWAN, respectfully announces that she has made arrangements to appear at the EGYPTIAN HALL, PICCADILLY, daily, in conjunction with the Siamese Twins and the Circassian Lady.

THE SIAMESE TWINS AND THE BEAUTIFUL CIRCASSIAN LADY are daily attracting crowded audiences at the EGYPTIAN HALL, PICCADILLY. Notwithstanding their great success they must shortly leave London for Paris. Public Receptions during the day as follows :—From Half-past Two until Half-past Four, and from half-past Six until Nine. Admission One Shilling.

N.B.—This will be most positively the last opportunity of witnessing the Siamese Twins in London.

DEFECTIVE ARTICULATION,

STAMMERING, WEAKNESS OF VOICE, &c.

THE REV. A. J. D. D'ORSEY, B.D., Lecturer at King' College, receives Pupil-Patients daily at One and Five, at 13 PRINCES SQUARE, LONDON, W.

THE MIDLAND RETREAT,

(Near Maryborough, on the Great Southern and Western Railway,)

FOR the Reception and Treatment of the Insane, and of persons suffering from a Disturbed state of the Nervous System, under the Direction of Dr. Jacob, Physician to the Maryboro' District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c. This Establishment consists of two separate and commodious residences—Anne Brook, for the reception of Ladies, Woolville for Gentlemen. Each situated on extensive grounds, with large, well-enclosed gardens. They are handsome, well-furnished country residences, where the patients enjoy the comforts and indulgences of a private house. The inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted, can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, and the North of Ireland.

MENTAL DERANGEMENT.—Orchardstown House, Rathfarnham. PRIVATE ASYLUM. The Patients receive every attention and kindness under the care of Mrs. STANLEY, Proprietress, and her family. Dr. HENRY CROLY, F.R.C.S.I., Visiting Physician. Terms moderate.

PRIVATE RETREAT
FOR
THE UPPER AND MIDDLE CLASSES
OF BOTH SEXES,
MENTALLY AFFLICTED,
TUE BROOK VILLA,
NEAR LIVERPOOL.

Vide page 1075, "Medical Directory," 1869.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

FOUNDED 1788. INCORPORATED BY ROYAL CHARTER 1864.

THE MEMBERS are reminded that a QUARTERLY COURT of DIRECTORS will be held on the 14th April next, at which candidates for admission into the Society can be proposed.

It is desirable that forms of proposal be filled up and forwarded to the Secretary at least a week before the meeting. the forms of proposal may be obtained of the Secretary.

The benefits of the Society are restricted to the families of deceased members of not less than two years' standing.

The Secretary attends at the office every Wednesday and Friday, from four to five o'clock.

J. B. BLACKETT, Secretary.

53, Berners-street, W., March 3, 1869.

COUNTY AND CITY OF CORK MEDICAL PROTECTIVE ASSOCIATION.

THE ANNUAL MEETING will be held at the ROYAL CORK INSTITUTION, on THURSDAY, 18th inst., when the Chair will be taken at Four o'clock. Members will dine at Seven o'clock on the same evening, Meeting and Dinner being open to the whole Profession.

By Order, CHARLES ARMSTRONG,
March 1st, 1869. Hon. Sec.

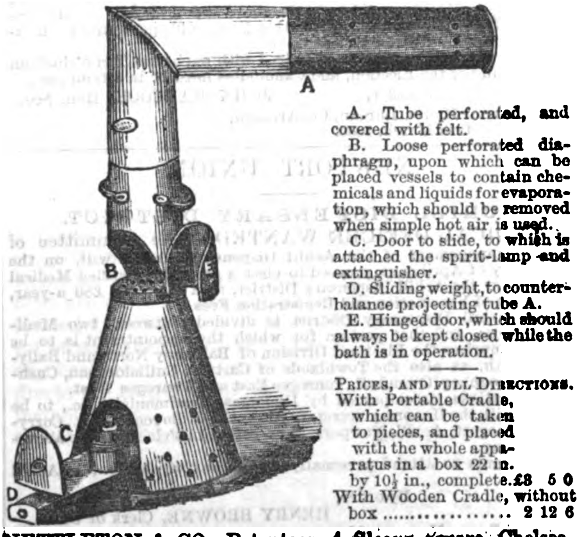
ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby given, that the next PRELIMINARY EXAMINATION will be held on WEDNESDAY, the 21st DAY of APRIL next, at 2 o'CLOCK p.m.

The following are the subjects upon which the Candidates will be examined, viz. :—The English Language, including Grammar and Composition ; Arithmetic, including Vulgar and Decimal Fractions ; Algebra, including Simple Equations ; Geometry, First two books of Euclid ; Latin and Greek, including Translation and Grammar.

By order,
JOHN BRENNAN, Registrar.

SURGEON-MAJOR WYATT'S
PORTABLE
HOT AIR AND MEDICATED VAPOUR BATH.



A. Tube perforated, and covered with felt.

B. Loose perforated diaphragm, upon which can be placed vessels to contain chemicals and liquids for evaporation, which should be removed when simple hot air is used.

C. Door to slide, to which is attached the spirit-lamp and extinguisher.

D. Sliding weight, to counterbalance projecting tube A.

E. Hinged door, which should always be kept closed while the bath is in operation.

PRICES, AND FULL DIRECTIONS.

With Portable Cradle, which can be taken to pieces, and placed with the whole apparatus in a box 22 in. by 10½ in., complete	£8 5 0
With Wooden Cradle, without box	2 12 6

NETTLETON & CO., Patentees, 4 Sloane Square, Chelsea.

DENMAN'S GREEK WINES, 20 PICCADILLY.

Priced Lists on application. **Sample Cases, 6 Red and 6 White Wines, £1 11s. 6d.**

RARE OLD WINES

FOR CONNOISSEURS.

Messrs. HEDGES AND BUTLER

INVITE ATTENTION to their extensive Stock of CHOICE OLD PORT,

selected and bottled with the utmost care, and now in the highest state of perfection, embracing the famed vintages of 1820, 1834, 1840, 1847. 1858, 1861, and 1863, ranging in prices from 42s. to 144s. per dozen.

WHITE PORT (very rare), 72s.; Pale and Brown Sherry, upwards of fifty years old, 120s.; choice old East India Sherry, 84s.; remarkably fine East India Madeira, very old in bottle, 96s.; Chateau Lafitte, 84s., 96s.; Chateau Margaux, 60s , 72s.; Steinberger Cabinet, 1834 vintage, 120s.; Imperial Tokay, fine old Sack, Malmsey, Frontignac, Constantia, Vermuth, &c.

WINES FOR ORDINARY USE.

Claret	18s., 20s., 24s., 30s., 36s. per doz.
Sherry	24s., 30s., 36s., 42s. per doz.
Port	24s., 30s., 36s., 42s. per doz.
Champagne	36s., 42s., 48s., 60s. per doz.
Hock and Moselle ...	24s., 30s., 36s., 48s. per doz.
Fine old Pale Brandy ...	48s., 60s., 72s., 84s. per doz.

FULL LISTS OF PRICES ON APPLICATION.

On receipt of a post-office order, or reference, any quantity will be forwarded immediately by

HEDGES AND BUTLER,
155, REGENT-STREET, LONDON,
And 30, KING'S-ROAD, BRIGHTON.
(Originally established A.D. 1667.)

CITY OF DUBLIN HOSPITAL.

DR. ARCHIBALD H. JACOB
will deliver, during the ensuing Session,
A FULL COURSE OF LECTURES
on the
DISEASES OF THE EYE AND EAR,
and the
OPERATIONS NECESSARY FOR THEIR TREATMENT.

LURGAN UNION.

MEDICAL OFFICER WANTED FOR THE MOYNTAGH SUB-DISTRICT OF THE LURGAN POOR-LAW UNION.—The Committee of Management of the LURGAN DISPENSARY DISTRICT will, at a Meeting to be held in the Dispensary, Lurgan, at Three o'Clock, on Thursday, the Ninth day of April, elect a properly-qualified Candidate to the above appointment. Salary (exclusive of Vaccination and Registration Fees), £100 per annum. Residence in the Sub-district indispensable.

Papers and Testimonials to be lodged with me before Ten o'clock on the morning of the Election, and Candidates must be in attendance.

By order, JOHN HANCOCK, Hon. Sec.
The Manor House, Lurgan, Co. Armagh,
12th March, 1869.

NEWPORT UNION.

ACHILL DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—The Committee of Management of the Achill Dispensary District will, on the Sixth day of April next, proceed to elect a properly qualified Medical Officer for the Achill Dispensary District, at a salary of £80 a-year, exclusive of Vaccination and Registration Fees.

The Achill Dispensary District is divided between two Medical Officers, and that portion for which the appointment is to be made comprises the Electoral Division of Ballycroy North and Ballycroy South, as also the Townlands of Cartron, Cuillalorghan, Cushlecka, Dooghbeg, Owenduff, Tonregee East and Tonregee West.

Applications, accompanied by Diplomas, Testimonials, &c., to be lodged with the Honorary Secretary, CHARLES C. BOYCOTT, Esq., Corrymore, Doogort, Achill, Newport, at or before 12 o'clock on the above-named day.

Applicants to attend personally on the day of election, at Achill Sound.

By order,
HENRY BROWNE, Clerk of Union.
Board Room, Newport, Mayo,
Feb. 26, 1869.

KINAHAN'S LL WHISKEY,

DUBLIN EXHIBITION, 1865.

This celebrated Old IRISH WHISKEY gained the Dublin Prize Medal. It is pure, mild, mellow, delicious, and very wholesome.—Sold in bottles at 3s. 8d., at the retail houses in London; by the Agents in the principal towns in England; or, wholesale, at 8, Great Windmill-street, London, W.—Observe the Red Seal, pink label, and cork branded "Kinahan's LL Whiskey."

MOST IMPORTANT TO FAMILIES· GUINNESS'S XXX PORTER.—J. BEBE invites attention to this Celebrated Porter in Bottle, being now specially ordered to invalids, for its nutriment and strengthening qualities; in fact it has been found, in great many instances, to supersede Wine in recruiting health and strength. Each Bottle is wired and tin-foiled, and is protected by his label and "Trade Mark." Prices are as follows. Terms Cash.

	Per doz.
Guinness's Celebrated XXX Porter (small bottles) ...	2s. 4d.
Guinness's Celebrated XXX Porter (large do.) ...	4s. 6d.

Ten Vans deliver daily in the city and suburbs, and orders sent by Railway to all parts of Ireland.

JOHN BEBE, Rectifying Distiller, Direct Wine and Brandy Importer
18. THOMAS-STREET, DUBLIN.

IMPORTERS AND PREPARERS OF MINERAL WATERS, etc.,

TO HER MOST GRACIOUS MAJESTY THE QUEEN IN IRELAND.

ESTABLISHED 1800.

A. & R. THWAITES & Co.,

INVENTORS AND SOLE PREPARERS
OF THE ORIGINAL
SINGLE AND DOUBLE SODA WATERS,
57 UPPER SACKVILLE STREET, DUBLIN.

—o—

SODA WATER (of two strengths, "SINGLE" and "DOUBLE") was invented by A. & R. THWAITES & CO. in the year 1799, and introduced to the Public by the late ROBERT PERCEVAL, Esq., M.D., then Professor of Chemistry, in his Lectures in Trinity College, Dublin, in 1800, since which time it has continued to receive the approbation of the Medical Faculty.

A. & R. THWAITES & Co.

present it to the Public as highly useful to the powers of Digestion; improves the appetite, stimulates the hepatic functions, without producing flatulency, and is particularly suited to persons of sedentary habits.

This Soda Water is prepared in Cisterns of Granite,
With strict attention to chemical accuracy,
And sold in 4oz. and 8oz. bottles.

—o—

In the year 1846 they obtained the following Certificate from the gentlemen of the Medicaal Profession:—

"We, the undersigned, have been for many years in the habit of employing the various Mineral Waters prepared by A. & R. THWAITES and Co., and willingly bear witness to the purity and accuracy of the preparations and the good effects we have witnessed from their administration."

(Here follow the signatures of thirty Physicians and Surgeons including all the most eminent of their day in Dublin.)

N.B. The knowledge of the chemical processes used by A. & R. T. & Co. in their preparations has NEVER been entrusted to any person in their employment, nor has it ever been imparted to ANY PERSON whatever who prepares Soda Water for sale.

Aerated Lithia Water.—Messrs. BLAKE, SANDFORD, and BLAKE, are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr. Garrod's instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA.—Also, Potash, Citrate of Potash, Soda, Seltzer, Vichy, and Mineral Acid Waters, as usual.

Blake, Sandford, and Blake, Pharmaceutical Chemists, 47, Piccadilly.

The Medical Press & Circular.

ON THE INFLUENCE OF NERVOUS POWER IN CONTROLLING THE TEMPERATURE OF THE BODY.

By NATHANIEL ALCOCK, L.C.P.I.,
Assistant Surgeon 35th Regiment, Portsmouth.

IN this paper I shall endeavour, as briefly as possible, to remind you of the most generally received notions of the origin of Animal Heat — the seat of its development and the means of its production—to point out its value in enabling us to understand physiologically the cause and course of some of those diseases in which its increase or depression forms a prominent symptom — and, in conclusion, I shall record a curious and I think instructive instance of the modification of temperature by the supervention of a second disease in a system already disordered.

As to the source, seat, and mode of development of animal heat—it is now generally accepted that "the blood itself is the seat of those chemical changes that develope force in the body." Force and heat are convertible terms, and therefore must the blood be the seat of the development of temperature as well as the means of its diffusion—the temperature of any part must then depend on two causes—on the amount of blood propelled into that part, and on the amount of chemical change going on in that blood—this latter is still almost amongst the unknown processes which we express as vital action—but the former we do know to be under the command of nervous power; though not under the control of the will. We know that in perfect health the ganglionic nervous system regulates the calibre of the arterial ramifications; which may, however, by any deviation from that condition be thrown into a state of morbid dilatation or diseased contraction; and that coincident upon such alterations an increase or depression of temperature, as a rule, ensues.

Bernard was the first to discover the remarkable increase of heat which follows section of the sympathetic—and Brown-Séquard showed that cold was produced by applying galvanism to it; thus proving that by suspension of the functional activity of the sympathetic system, and simultaneously with the consequent dilatation of the capillaries of the part, heat was developed: whereas by the stimulation of the functional activity of the same ganglia, and during the resulting contraction of the capillaries, heat was decreased.

Experiments such as these, and with like contrasting effects, are, I believe, repeated in the human constitution during those disordered conditions which we term Heat-stroke and Cholera.

It is, however, but a mechanical part which the capillaries play in the development of heat subject to the control of the nervous system. For the primary source of animal heat we must look to those mysterious vital processes, so beautifully described by Professor Lionel Beale, during which the pabulum in the blood is appropriated by the existing germinal matter to be changed into formed material, no longer living; but which, when it has served its purpose in the economy, is to be thrown off as effete. We infer that the process of forging pabulum into formed material can only be carried on in the presence of a certain temperature—that that temperature has been originated by the gift of heated blood from the mother to the fœtus, and maintained throughout subsequent independent life by the consumption of its own waste tissue, or formed material; and here the question arises if in the act of assimilation of pabulum by the germinal matter any heat whatsoever is evolved, or whether heat is solely due to the consumption of formed material—destructive metamorphosis so called. Professor Lionel Beale, in the report of his investigations into the cause of the late Cattle Plague, which he attributes to morbid unclear corpuscles introduced from without and multiplying in the blood, says, "that as while this increase of germinal matter is taking place the temperature rises, so it is probable that the elevation of temperature in this, as well as in fevers and in inflammations generally, can scarcely be due to increased oxidation, for both the circulation and respiration are often seriously impeded, but must be attributed rather to the phenomena occurring during the increase of the germinal matter and connected with this increase."

I should, however, be more inclined to think that the augmented heat was due to the increased amount of fuel supplied to the natural furnace by the rapid decay of these hurriedly formed and short-lived morbid germs—and as heat is apparently an indispensable agent in the process of nutrition, to attribute to destructive metamorphosis alone the duty of maintaining the temperature—and even going farther to surmise that in the process of healthy nutrition heat is abstracted and rendered latent by the growing atoms of our bodies. This too helps to explain how on the arrest or diminution of nutrition, and the increase of destructive metamorphosis, the outward manifestations of heat are more marked; since not only is the amount developed greater than natural, but less is retained for internal use.

Præternatural heat, then, is the result of three conditions—suspension or exhaustion of the functions of the sympathetic—perverted nutrition, and increased metamorphosis—but the second and third I believe to be consequences of the first, and that excess of temperature local or general is an evidence of exhaustion of the functions of the sympathetic of that part or of the whole system.

Seeing, therefore, that the organic nervous centre presides over the regulation of temperature, and knowing how intimate and inscrutable is the connection between this and the nerves of animal life, by which we think, move, and feel, we can readily comprehend how each must act and react on the other—how the shock of the sudden and distressing intelligence of to-day, causing at the time, shuddering, pallor and syncope, signs of an irritated sympathetic, may to-morrow be followed by delirium and fever—or conversely how the invasion of some subtle atom of germinating poison among the organs of organic existence will subsequently overturn the balance of the functions of animal life.

That the nervous centres exercise a direct influence over the waste of tissue, causing an expenditure of substance beyond what is required for maintaining the natural temperature and supplying force equal to a full day's muscular work in addition, is, I think, clearly proved by Professor Haughton in his address before the British Medical Association "on Food and Force"—in which he shows that a ram during the rutting season excretes six times as much urea as at other times when he ceases to be the subject of nervous excitement. He also establishes by direct calculation "that the whole work done by the muscles, voluntary and involuntary, of a hard worked labourer will amount to less than one sixth of the work expended in maintaining the temperature of his body at 100°," that the total value of the force expended by a man weighing 10st. 10lbs. in the double duty of performing a full day's work and maintaining his own temperature would equal the work required to raise his own body through a vertical height of eight miles—and from this by a simple calculation he deduces the fact that a patient who has borne the burden and heat of a day of fever at a temperature of 105°, is at its close in the position of a man who not only maintained his natural heat, and also performed the duty of a hard worked labourer, but in addition to, and worn out by, the foregoing, then accomplished the feat of raising his own weight through a vertical height of one mile.

We can from this comprehend the enormous outlay of tissue required to meet the demands of fever, and cease to be surprised at the rapid emaciation and exhaustion which follow in its course.

Now, as to the nature of that disease the symptoms of which I believe to be typical of an exhausted sympathetic, viz., heat-apoplexy, or heat-stroke, Dr. Handfield Jones, in a communication read before the Harveian Society last October, says "that heat, when it becomes at all excessive, is enfeebling to nerve power, and that persons endued with much nerve force resist heat much better than those more feebly constituted;" and again: "I cannot but believe that the primary nerve disorder in heat-stroke is of a functional kind, and that all the grave symptoms which ensue may be independent of any structural lesion." In this I perfectly agree; and, in support of this, I offer you the following analysis of eleven cases of heat-stroke which occurred in the 35th Regiment during its sojourn of three years in Mooltan, the hottest station in India. In these, with one exception, there is a distinct history of nervous exhaustion prior to the attack.

3rd July, 1865.—Sergeant W. Gordon. In hospital for a fortnight with intermittent fever. Died at 7.30 p.m.—10 hours.

3rd July, 1865.—Private Tapper. Had been working in regimental garden to a late hour in the morning; attacked in barracks. Died on way to hospital, at 7.30 p.m.

3rd July, 1865.—Private Browne. Had marched with his company from cantonments to fort in the morning; attacked in fort at 10 a.m. Died 7th instant—99 hours.

3rd July, 1865.—Private McCabe. Also marched with company to fort in morning, was put on guard, and after two hours sentry-go was seen to be confused and strange; attacked at 3 p.m. Died on the 5th—33 hours.

3rd July, 1865.—Private L. Hurst. Also marched to fort on same day; suffered from pain in vertex, nausea, and vertigo; symptoms of insolatio not fully developed till the 8th. Recovered slowly, but eventually invalided for cephalæa.

5th July, 1865.—Private W. Taylor. In hospital under treatment for chronic rheumatism; much debilitated. Died on July 6th—28 hours.

9th July, 1865.—Colour-Sergeant H. Ashwin. In hospital for intermittent fever; had been drinking more than usual for some time before admission. Died on the 10th, at 3 p.m.—11 hours.

21st August, 1865.—Private L. Armstead. Attack lasted five hours, but rapidly recovered.

22nd August, 1865.—Private Mackay. In guard-room for being drunk; confined an hour before seizure. Died in 10 hours.

25th June, 1866.—Private Shea. Admitted in morning for fever; had run four miles behind a cart on previous evening; attacked in evening. Recovered.

24th May, 1867.—Private Mercer. Had severe diarrhœa for three days before attack. Recovered.

In the first five cases, all of which occurred on the same day, two had been debilitated by previous disease, and three by physical exhaustion, having belonged to the company that marched from cantonments to relieve another company in Mooltan Fort on that morning; and this is rendered still more remarkable by the fact that, although these three men who marched to the fort in the comparative cool of the morning were seized, yet none of the relieved company, which returned from the fort to cantonments at a hotter and later hour of the day, were attacked. This, I think, may be explained by considering that those who went to the fort were obliged to be put on duty at once, thereby keeping up the process of exhaustion already begun; whereas those who returned to cantonments were off duty for the day, and were thus enabled to rest and recruit themselves.

In the six succeeding cases there is but one exception in which fatigue, intemperance, or previous disease had not depressed the vital powers.

I therefore regard the affection as one in which the vaso-motor nerves and their centres being enfeebled and relaxed by the above influences, the superadded effect of intense heat, by pushing that exhaustion to the verge of paralysis—analogous to the experiment of section of the nerve—gives rise to the symptoms of heat-stroke.

Since writing the foregoing I found in the last number of the Medical Press and Circular an account of a case where a French surgeon, in excising a tumour from the neck, destroyed the "great sympathetic and phrenic branches" on the right side.

On the following day the face, especially on the right side, was deeply congested; the pupils unequal, the right being strongly contracted; the breathing hurried and oppressed.

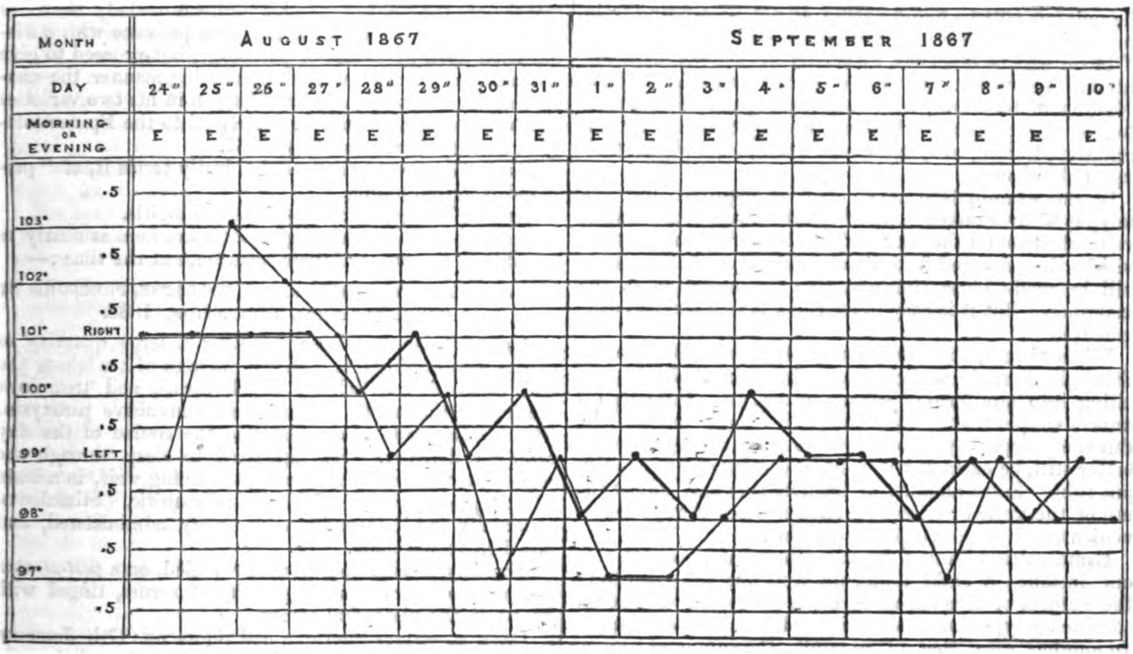
On the next day there was diminished respiratory murmur up to the middle third of the right lung; pulse 120; and on the fourth day the lung became dull throughout the lower two-thirds; coffee ground vomiting set in, and the patient died.

The *post-mortem* showed pleurisy and congestion of both lungs.

Here, then, are two marked features in common between the divided sympathetic and heat apoplexy, as described by Drs. Aitken, Parkes, and others, viz., greatly contracted pupils, and excessive engorgement of the lungs.

In conclusion I offer you the thermometric record of a case which occurred in my own practice in India, in which excessive uterine hæmorrhage, consequent on abortion, gave rise to temporary paralysis of the right side, as evidenced by loss of muscular power and lowering of the natural temperature.

A couple of days subsequently fever, to which she had been previously subject, came on, and then the temperature on the paralysed side rose considerably above even the fever heat shown on the sound side, thus proving the elevation of temperature on invasion of disease to be in direct proportion to the previous nervous depression.



Under the use of stimulants and quinine the disease abated, and the heat on the paralysed side soon sank below that of the other, both, however, accurately following the rise and fall of the intermissions of the fever, and gradually approaching each other till they became again equal on convalescence being established.

Of the clinical use and practical value of facts such as these, it would be presumption for me to dilate further in an assembly like the present.

◆

ON POLYPI OF THE RECTUM.

By Holmes Coote,

Surgeon to St. Bartholomew's Hospital.

A surgeon now in practice once informed me that polypi of the rectum were so common that cases came almost weekly before his notice. On the other hand, the late Sir W. Lawrence assured me that he had never seen such a case. That polypi in this region do exist, cannot, considering the authorities which can be quoted in support of the fact, be reasonably denied; but the cases are rare—much more so than some surgeons would lead us to believe.

In the first place, malignant diseases should be excluded from this subject. A "malignant" polypus is a term as much out of place when applied to the rectum as it is when applied to the nose. A polypus should mean a firm, pedunculated, fibrous, or fibro-cellular growth, springing from the interior of the rectum, and covered by its mucous membrane.

But in 1860, Stoltz directed attention to this affection as occurring in children. Since 1842 he had observed four cases, aged respectively, eleven, four, five, and eight years; and this, perhaps, would somewhat agree with the experience of my friend Mr. Marsh, of the Children's Hospital. Mr. Bryant has detailed the particulars of a case of polypus of the rectum in a child, successfully removed (*Lancet*, Oct. 27, 1860), and to this is appended another of firm, fibrous polypus, occurring in an adult. Kronenberg relates four cases of this affection in children (*Journ. f. Kinderk*, 1861), and Hulke relates a case (*Med. Times and Gazette*, Nov. 30, 1860).

Syme speaks of three forms of polypi—first, a vascular, deep red-coloured structure, resembling a worm or leech, as described by the late Sir Astley Cooper; secondly, a soft, vascular, lobulated growth, shreddy and malignant-looking, and prone to bleed, but possessing a peduncle sometimes capable of sound cicatrisation after being divided; and thirdly, a firmer tumour, with smoother surface, and more regularly spheroidal, or oval in form.

Whether polypi of the rectum occur more frequently in the adult than in the child may still be a matter of doubt; but the latter view is the more general. Mr. Ashton, however, has met with only one case in a child.

The symptoms of polypus of the rectum are at first obscure, but, according to Mr. Bryant, hæmorrhage from the bowel in children is a very certain indication of its existence. "Since 1859," he says, "many such cases have fallen under my care, and I must confess it is a rare thing for me to meet with any instance of hæmorrhage from the bowel in children which is not to be explained by the presence of such a growth. They are generally found in children under ten years of age (*Brit. Med. Journ.*, 1863); when the bloody discharge is constant," he adds, "and the buttocks are stained with a bloody mucus, the polypus will be found within, if not protruding from the sphincter. In other instances, occasional discharges of blood will be observed, especially at each act of defæcation. The weight and size of the polypus may produce a feeling of tenesmus, with occasional spasmodic contraction of the sphincter. The patient may also suffer from irritation, leading to symptoms of diarrhœa, and to a feeling of flatulence.

In the examination much care is required, lest the polypus be overlooked. Mr. Bryant "sweeps the finger, well oiled, round the walls of the bowel." The polypus will be thus dragged from its attachment, and its pedicle will be made tense, thus arresting the attention of the examiner. But it is easy to overlook it in a careless examination.

When found, they had better be removed at once, although there is no fear, I apprehend, of their degenerating into any form of cancerous disease. In many instances simple traction will suffice to detach the pedicle. But the polypi may be often removed by the ligature, or, better still, be extracted by a small écraseur, or wire polypus-tube. Some amount of hæmorrhage may follow the use of the knife or scissors, a circumstance always inconvenient, and to be avoided if possible.

Examinations cannot be too minute and careful. In one instance a child under my care was supposed to be the subject of this affection, when it was found that the so-called polypus was the undigested core of a large apple. In another case, that of an adult, the supposed tumour proved to be a portion of intussuscepted bowel. But so closely did it resemble a large and firm growth, that an operation had been recommended, and the true nature of the case was first detected by the central opening which led to the inverted intestinal tube.

◆

CASES, WITH OBSERVATIONS, OF PUERPERAL PURPURIC FEVER.

By Evory Kennedy, M.D.,
Ex Master of the Rotundo Lying-in Hospital, Dublin.

(Written in August, 1867.)

I offer no apology for occupying the attention of your readers for a short time with those cases of zymotic disease which occurred in the Dublin Lying-in Hospital in the spring of the year 1838, and which evinced the characters exhibited in the so-called purpuric or cerebro-spinal fevers recently occurring in Dublin. In the year 1838 that scourge of parturient females *puerperal fever* visited our great Lying-in Hospital here with peculiar malignity, and carried off thirty-five patients between the months of December, 1837, and April, 1838.

In the progress of its ravages on that occasion, cases occurred of a nature so entirely different, and so unlike any of those I had seen before, or, indeed, subsequent to this epidemic, that it will be in the recollection of others that I produced morbid specimens and drawings illustrating them at the Pathological Society at the time. Unfortunately these drawings are mislaid, but the cases, as recorded at the time of their occurrence, are available. A few of the most striking of these I have abbreviated, giving merely an abstract of their most prominent features, omitting nearly all treatment for the sake of brevity, and stating the morbid appearances in such of the cases as dissection could be obtained. But my younger readers must bear in mind the fact, that twenty-eight years ago dissections in hospitals were very difficult to obtain. They could not be effected without the consent of friends, and an examination of the head and spinal marrow it was nearly impossible to gain consent to.

So much has been said and written within the last few months on the subject of this protean malady that has shown itself, that I shall not tax your patience with a disquisition upon its nature or pathology, but proceed to give the cases, exhibiting in the most striking manner the characteristics dwelt upon by Dr. Marston in his two varieties or classes, as put forward in his report to the Epidemiological Society on the 1st July, 1867.

First. Those expressive, as he justly terms it, of "profound blood-poisoning."

Second. Those of cerebro-spinal meningitis.

I should mention that I give the cases here as nearly as possible in the order of their occurrence at the time:—

PUERPERAL FEVER, WITH RAPID COLLAPSE, PRECEDED BY CEREBRO-SPINAL IRRITATION, 1838.

Anne Whelan had been drinking a large quantity of spirits before admission. In the progress of her labour she had convulsive twitchings of the arms, and tremulous motions of the hands, and a slight convulsive paroxysm. This woman made no complaint in the course of the day after her delivery. She appeared to sleep through the night, but was found, at the next morning visit, in a state of collapse, with her abdomen tympanitic. Stimulants, externally and internally, were freely administered, and she died in six hours.

The only morbid appearances revealed, on a *post-mortem* examination were a small quantity of serum, tinged with blood, in the peritoneal cavity.

Case 2.—Mary Sheridan had rigors on 17th January, 1838. Pulse 120. No local pain—(three days delivered.) On the 20th, at two o'clock in the morning, had an attack; pronounced hysterical, with marked globus; crying and laughing. At eight o'clock she fell into a state of stupor, with stertor, and remained comatose until four p.m., when she expired.

Post-mortem appearances.—The omentum and peritoneum opaque and covered with lymph; a pint of milky serum in peritoneal cavity; lungs coated with plastic lymph, congested and crepitating. Both pleural cavities filled with flaky lymph adhesions; transparent serum in pericardium; right auricle filled with fibrine; blood fluid; uterus soft and easily torn; ovaries embedded in lymph; subarachnoid effusion and effusion into ventricles.

The dissection here fully evidences the existence of puerperal fever. Now, this fact becomes the more important, when we draw the analogy we attempt between the recent typhus and the puerperal epidemic of 1838. Sheridan's case is one of several that have occurred to me in puerperal fever, in which the hysteric complication furnished an unfavourable prognosis. The same fact has been dwelt upon by Cheyne and Graves, and more recently by Hudson, when hysteria occurs in fever. The latter astute physician connects its occurrence with suppression of the menses.

The next case we shall give, is one in which head symptoms were also very markedly observed to complicate the fever, which ran to a more chronic form, with consecutive arthritis.

CEREBRO-SPINAL PUERPERAL FEVER, FOLLOWED BY ARTHRITIS.

Mary Lynch, delivered on the 30th January, 1838, was attacked by rigor on the 3rd February, with fibrile symptoms; much flushing; pulse 130; some abdominal pain.

On the 4th delirium set in, with great restlessness, anxiety, and spasmodic respiration, headache, and rapidity and indistinctness of articulation.

5th. Delirium continues, with headache, more distressing in occipital region. She struggles to get out of bed. Tongue streaked red ; peculiar exhalation from tongue and mouth ; sickness.

6th. Violent and incoherent muttering, but answers rationally when addressed ; pulse 136.

7th. Raving and starting ; a quantity of vapour issuing from the mouth ; less complaint of head, but complains of abdominal pain, and of pain in left arm ; pulse 144.

8th. Slept well ; no delirium ; asks for drink ; pulse 136 ; elbow-joint engaged ; tender, swollen, hot, and red ; stick nitrate of silver freely applied to it.

9th. Delirium returned in the night ; stupor and muttering ; elbow more swollen ; left knee and bursa engaged ; retention of urine.

On the 10th, the arthritis extended to the wrist ; diffuse inflammation seized upon the buttock and the parotid gland ; and the case assuming the characters of consecutive arthritis, and terminated fatally with effusion into pleura, on the 15th.

We have now to deal with the dark discolouration observed in these cases. The whole question of these, as well as in puerperal typhus, purpuric typhus, purpura, as in cholera, demand elucidation.

The hæmorrhagic and scorbutic complications, to which it is referred, give us little assistance, and, with Flint, I have little doubt that its explanation must be looked for in the capillary system, and, perhaps, in the blood itself.

TRAUMATIC PUERPERAL GANGRENE.

Margaret M'Gouran, æt. 32, who was doing well for two days after her delivery with the forceps, in consequence of tedious labour, was attacked on the morning of the 2nd of March, 1838, by cerebral symptoms, with rapid pulse and slight abdominal tenderness. Her excitement was so great that she became unmanageable, and was obliged to be restrained in bed. She complained incessantly of pains in her legs. The whole surface of the body, but more especially the face and lower extremities, became livid. Large blue coloured bullæ, or vesicles, appeared on different parts on the lower extremities, as may be seen in plate No. 1. The excitement subsided in a few hours into a state of depression, and she sank at noon on the 3rd, about twenty-eight hours from the commencement of the attack. Only an abdominal examination could be obtained of this case, when a small quantity of bloody serum was found in the peritoneal cavity, and some sloughing in the vagina, due no doubt to the instrumental delivery and justifying its being referred to the class "*Traumatic*." This drawing is an accurate delineation of the left lower limb, taken within a few hours after death, and not sensibly altered from the appearance it presented during life. The section of adipose tissue was taken from the abdominal parietes, and furnishes an idea of the congestive infiltration that prevailed throughout the surface of the body.

The black serum brings to recollection my old friend Dr. Alison's case of the black fluid in the blistered vesicles.

FEVER WITH BLUE DISCOLOURATION OF SURFACE.

Mary Carton, æt. 27, was attacked on the 11th of April, 1838, three days after a natural delivery, with aching abdominal pain—quick pulse, and high state of excitement. On the 12th, pulse 134 ; expression of countenance, bad ; hands and feet blue.

13th. Blue tint extends to face and trunk ; pulse almost imperceptible ; respiration gasping ; little abdominal suffering, unless on pressure.

14th. Sinking, died at ten a.m., fifty-six hours ill. No *post-mortem* examination permitted.

PUERPERAL FEVER, WITH DISCOLOURATION OF LIMB, VESICLES, GANGRENE, AND COLLAPSE.

Biddy Fox, æt. 30, was seized with rigor, followed by febrile excitement on the 5th of May, 1838—the fifth day after her delivery of a seven months' child, caused by fright. She had only been three hours in labour. The fever continued without any local affection or abdominal tenderness ; throughout the 6th, and at three a.m. of the 7th, she was seized with acute pain in the calf of the left leg. At morning visit her state was as follows :—Countenance anxious, and expressive of suffering, and great constitutional disturbance ; pulse small, 96 ; calf of leg swollen, tense, and acutely painful on slightest touch ; no pain up thigh, but some uneasiness on deep pressure, low on left side of abdomen ; skin hot ; constantly crying about pain of leg ; twelve leeches were applied to the calf of leg ; at one p.m. the limb become discoloured, the discolouration gradually extending up the thigh and down to the ankle and foot, where vesications rapidly formed. Some punctures were made in the calf of the leg and popliteal space, by my able colleague, the late Surgeon Abraham Collis, in search of matter ; but the pulse became rapid and indistinct, and she rapidly sunk, and expired at seven p.m., fifty-six hours from the occurrence of the rigor, and sixteen hours from the seizure of the limb. The femoral and tibial arteries continued pervious throughout, and the temperature of the left limb was higher than that of the right.

No examination permitted.

PUERPERAL FEVER, WITH GANGRENE OF UTERUS: SYMPTOMS PRECEDING DELIVERY.

Mary Anne Brennan was admitted at 11 a.m., on the 8th Jan., 1839, in the ninth month of gestation. About two o'clock the pupil on duty reported that she complained of great pain in her right thigh. On examination it was found large, tense, very painful along the course of the rectus muscle ; but tenderness did not extend upwards as far as the saphena vein. There was also some soreness in the right iliac fossa. Pulse quiet and small ; tongue furred. States that about a week before she had had a rigor, followed by sudden loss of power in right leg, and that yesterday she had another shivering fit. Twelve leeches were immediately applied to the limb, and within an hour she expressed herself much relieved. At half-past five o'clock p.m. she was conversing with the nurse, when she was observed suddenly to sink, her arms becoming powerless. Notice was immediately sent to the assistant on duty, who found her pulseless, eyes glazed, feet cold, features collapsed—in fact, moribund. Stimulants were administered, but she expired in a few minutes.

The Cæsarean section was performed, and the child removed, but it exhibited no signs of vitality, nor could its heart's action be detected at the moment of the mother's death.

On drawing backwards the abdominal parietes, the uterus exhibited the appearance represented in this drawing (No. 3). The ovary and Fallopian tubes, particularly on the right side, were gorged with blood, and the structure of the uterus in their immediate neighbourhood was dark and softened—in fact, in a state of ramollissement. The fimbriated extremity was glued by soft, freshly-effused lymph to the peritoneum.

The following cases, passing into erysipelas, purulent depots, cellular sloughs of the character of anthrax, and arthritis, show more strikingly how puerperal fever, like typhus, is ascribable to a poison which vitiates the blood and passes through a series of consecutive stages, due to what are termed poison depots in various parts of the body.

Mary A. Keating was seized, on the 10th of December, 1837, with erysipelas of the elbow-joint, on the tenth day after her delivery. The solid nitrate of silver was freely applied to it, with relief. The buttock became engaged on the 12th, and the nitrate of silver was freely applied. The pain, which was intense, was relieved. She had much prostration, diarrhœa, and rigors, at intervals, and great nervous anxiety. Potassa fusa was now applied to the buttock.

The inflammation here became circumscribed, and, on the 17th, the sterno-clavicular articulation became engaged.

Not until the 29th could matter be detected in the buttock, when a puncture was made. Some matter escaped, and ultimately a mass of sloughed cellular tissue separated. She gradually improved, the joints engaged, returning to their natural state, and she left the hospital on the 4th of January, becoming convalescent.

See No. 9 drawing, which represents a limb in which similar depots occurred.

In some of these cases the symptoms of diffuse inflammation set in as the primary poisoning, even showing themselves before delivery. In these, the great joints were those principally attacked, and the pain was excruciating.

The inflammation was so rapid, immediate, and destructive in its character, that I was induced, in some, to try the actual cautery, particularly when the sacro-iliac synchondrom was affected.

In those cases in which it was tried, although it did not succeed in curing, it seemed to arrest the progress of the diseased action, and the patient, in each case in which it was had recourse to, expressed herself as markedly relieved from the agonizing pain, and that, after the fullest opiates had been administered in vain.

The only treatment I found of service in these local and arthritic inflammations was the free use of nitrate of silver escharotics in the milder, and potassa fusa, and the actual cautery, in the more urgent cases.

The hopeless character, however, of the more urgent cases, in which the large joints and adjacent structures take on this poison action, were at once seen, by looking at the specimens, which exhibited the trochanter eroded by ulceration, the two hip-joints engaged, the sacrum in a state of destructive ulceration, whilst the soft parts of the upper part of the thigh and gluteal muscles were in an advanced stage of ramolissement, and those on the left absolutely sphacelated. Surely, if ever the true *εσθιομενος* of the Greek fathers in medicine, justifying the synonym of the Latin, *exedens*, *depascens*, *corrosivus*; is to be found in modern pathology, we have it here.

Admitting then that puerperal fever, like typhus, is the product of a poison, only modified by the state in which it finds its victim, which, in the puerperal condition, directs its ravages primarily to those tissues most directly affected by the engrossing functions of the moment—we can well understand how the uterus and peritoneum should be the organs affected by the poison in puerperal fever generally. The poison may, however, be occasionally so modified in its essential character, or, what is perhaps more likely, a certain condition may prevail at a given time, either in the atmospheric or other influences without the body, or in the nervous, circulating, or nutritive systems within, which would determine the morbid action, as lately seen in typhus, and in puerperal fever in 1838, to the cerebro-spinal system, and thus give rise to a similar modification of symptoms in both. And further, according to the continuance or discontinuance of the cooperating causes productive of the modification would the new disease cease or be perpetuated. In this way might be generated a new variety of an original morbid principle, transmissible as a personal, contagious, or generally diffused poison.

The record of the above cases is so far conclusive in a pathognomic point of view, that throughout them all, one and the same fever, namely, puerperal fever, constituted the unmistakeable and ever-present essence of the diseased action, by which the patient was grasped. And further, the essential proofs of this disease were in no case absent. Yet those conversant with puerperal fever upon a somewhat extensive scale, must admit that morbid complications in addition existed, in these cases, with which they are not familiar, perhaps not even acquainted. The natural and incontrovertible inference then is, that the complications recorded constitute varieties grafted on the original diseased action, depending upon influences prevailing, no doubt, at the moment, which influences evade our detection, although their results are so palpable and apparent. The whole subject of zymotic diseases—their causes, spread, varieties, types, upon what subtle agencies depending—is so complex and obscure, that, as yet, we are but on the threshold of its investigation. If we are to arrive at any sound knowledge upon them it will be by observing closely their general laws, which can only be done by comparison of new forms or varieties with those epidemics that have passed, and the relations of both with persistent or enduring diseases with which we are familiar. I cannot illustrate this necessity on the conclusions I have long arrived at better than by transcribing here a question put to me by a Medical Commission, who were engaged in inquiring into the state of the hospitals and sick poor in the year 1840, with my answer :—

Query —" Does puerperal fever appear to have prevailed more extensively when any general epidemic has prevailed in Dublin ?"

Answer—" Yes ; I have remarked that when continued fever, typhus, or erysipelas, were prevalent in the Medical and Surgical Hospitals, puerperal fever appeared to prevail in the Lying-in Hospital, as well as in the city generally. The character of the fever varied also at different times, and occasionally appeared to be influenced in its nature by any prevalent epidemic."

Sydenham and other authorities have long established the fact that fever at different times and places may be characterized by peculiar and various local tendencies. And science, it is remarked, is no better prepared to explain their occurrence now than at any past period in medical history. By some, these varieties are merely considered complications or inter-current symptoms ; by others pathognomic essentials, which justify the conclusion that the diseases are distinct in cause, symptoms, history, and pathology, and ought, consequently, to be so in name. In investigating both the predisposing and occasional causes which exist without the body of the diseased person the " *circumfusa*," " *ingesta et applicata*," arising from the influence of external bodies, we too frequently lose sight of the assistance to be gained from the study of "Epizotia" or diseases of animals. In epidemic and contagious diseases this is much to be regretted. It was long since remarked by Guersant, that the circulatory and nervous systems of warm-blooded animals approach nearly to our organization, and their diseases present an analogy with ours. "The essential and symptomatic fevers ascribable to excitation of the nerves and blood-vessels, and the reaction of these organs upon each other, occur in them, and especially in the mammalia, with the same characters, and almost the same names. The resemblance between *their* maladies and those of *man* are sometimes so perfect that it is impossible not to place them in the same " nosographic cadre," and not to assign them the same name. The discrepancies of opinions upon a name to be appropriated to the late epidemic might have been reconciled or harmonized had the phenomena observed in some of the epidemics which have prevailed amongst animals been looked to. For instance, in the epidemic typhus, which prevailed amongst horned cattle in France in the year 1795, as well as in that of 1814, M. le Professor Dupuis constantly observed " that the spinal marrow was more injected and soft than natural, that the meningeal coverings were red, and contained, in their folds, a large quantity of limpid and transparent serum, and, in the lumbar region, the medulla was softened, and the cellular tissue of the lumbar and sacral nerves gorged with blood-serum. The brain in these animals dying of typhus was not so often observed softened as the medulla, but sometimes the meningeal coverings were more injected and red, and the ventricle often filled with a quantity of citrine serum."

Cerebral symptoms have also been observed in epidemic catarrh of dogs, assuming, in its progress, the form of epilepsy, or dance of St. Guy. Edward Jenner tells us of a gentleman who killed several of his dogs labouring under this disease, supposing it hydrophobia. Dissection displayed a soft brain ; the ventricles full of serum, and the medulla softened, and fluid in its membranes. The "epizootic charboneuse" or typhus of domestic fowl, which prevailed in Paris in 1780, and whose chief complications were gangrenous angina and ophthalmia, was accompanied with convulsions of the wings, and other parts of the body, and the bird expired after a rattle of a peculiar kind, apparently convulsive, which resembled a plaintive cry proceeding from the bottom of the throat, not unlike spasmodic croup. On dissection, the brain was found gorged with blood, the interior of the bill and pharynx and external parts gangrenous, and ecchymosis in the different viscera.

We adduce these cases to show that, in the animal, as well as man, modifications of known diseases occasionally occur, as in the puerperal cases observed by me in 1838, as well as in the later cerebro-spinal cases, *intercurrent* with the ordinary disease. The original type or generic characters prevailing and existing, whilst the varieties assume a more a less prominent position, throughout its progress. Where these occur, as we might say, accidentally, in a peculiar epidemic, as, for instance, in the five cases of parotiditis out of thirty-five recorded by Dr. Flint, and leave no permanent distinctive features, merely cropping up sporadically subsequently; they should be treated as complications due to causes in operation at the moment, evanescent in their nature, and in no way necessary to characterize the case, therefore, unworthy of a special name. When, however, on the other hand, we have a train of symptoms nearly constant in their occurrence, such as a peculiar eruption present, a peculiar structure engaged; non-contagious in its nature, not transient, not accidental in its occurrence, but permanently established amongst us, and traceable, as it is often, to cognate causes; then I think we must grant such a train of symptoms a right to be considered a distinct disease, and endow it with a special name, as we have done in the case of typhoid or enteric fever.

It remains still to be proved whether the group of symptoms observed to occur in the recent epidemic shall recur and become permanent, as has been the case in enteric typhoid, or whether they will assume those distinctive marks which have so isolated the latter disease, the very name applied to which evinces that it exhibits generic characters that assimilate it to a parent type.

The non-recurrence for nearly thirty years of an epidemic exhibiting the same characters as the cases described by me in this paper as purpuric or puerperal typhus, would lead us to hope that such may possibly be the case as regards the recent cerebro-spinal epidemic also, and, consequently, that, failing in its element of permanency, it might only be referred to hereafter as a form of typhus prevailing for a short time in the spring of 1867, and limited to a small number of cases, attended with cerebro-spinal symptoms, discolouration, and collapse, and which may take its place with the puerperal typhus of the Dublin Lying-in Hospital of 1838, with epidemic typhus amongst horned cattle in 1795 and 1814, and with the typhus charboneuse in domestic fowl of 1780—all of which partook more or less of the same pathognomic characters.

Note.—The references to the drawings have been given in the text as there is reason to hope they will be found, and published shortly.

CONTRIBUTIONS TO CLINICAL SURGERY AND MEDICINE.

By William Hargrave,
Professor of Surgery, Royal College of Surgeons, &c.

(Cases taken by Mr. Donaldson, Resident Pupil.)

(Continued from page 204.)

EXTRACTION OF A NEEDLE FROM THE LEFT INGUINAL REGION.

Emily V., æt. twenty-four, was admitted into the City of Dublin Hospital, April 23rd, 1868. States that about five weeks ago, whilst engaged in sewing, a person fell on her accidentally, and caused the needle she was sewing with to pass into the vicinity of the anterior superior spinous process of the ilium (the upper part of the needle breaking off); she then manipulated it down with her fingers into the left inguinal region. In about a week after the occurrence the part became painful and swollen, and an effort was made by a doctor to come down on the needle by incision, but without effect; she then poulticed it with linseed meal, and it ceased to give her any trouble until admission, or a few days before, when the pain became very severe, especially during the motion of the limb. On May 2nd she was placed under the care of Dr. Hargrave, who was unable to feel the needle; she was ordered to walk about the ward, in the expectation of its being brought nearer to the surface. May 13th the needle was indistinctly felt; a free incision was made over it, but owing to the violent struggles of the patient the endeavour to find it was abandoned, but the needle was evident. On the 18th, the patient *being fully under the influence of chloroform*, which was accomplished with some difficulty, an incision was made two inches long over the situation of the needle parallel to the common femoral vein, dividing both the superficial and fascia lata, after a little searching, it was found imbedded in a gland, the point projecting to the integuments; it was then extracted, and measured three quarters of an inch in length. The wound was then dressed. This patient was so powerfully affected by the chloroform, that nearly one hour was occupied in rallying her from the effect of it, after having recourse to the usual means for that purpose; it was not till the application of galvanism she completely recovered from the perilous position she had been placed in by the anæsthetic agent. In the very few instances in which I have been compelled to use galvanism for the purpose now specified, I *always* strike one pole into (if possible), the left phrenic, and always into the anterior scalenus muscle, the other pole into the diaphragm on the left side; by selecting this side, not alone for its convenience, I go nearer to the heart, and by so doing can recall it to its natural state of action, so that the respiratory and circulating systems are called *pari passu* into action.

For thirty-six hours she suffered from intense headache, after which everything went on most satisfactorily, and was discharged the hospital, June 19th, convalescent. I may further remark, but for chloroform being so decidedly, even dangerously, administered, as the sequel of the administration has shown, I do not think that the needle could have been extracted.

The following case of a needle imbedded in the right side of the neck of a young girl about twelve years old, may not be devoid of interest. She applied as a dispensary patient in the summer of 1868, complaining of a hard painful substance immediately behind the right sterno-mastoid muscle and subcutaneous to it. On examining this region I found something like a hard foreign body perfectly moveable in every direction. I made an incision over one end of it, and immediately extracted a broken needle one inch and a half long, which is still in my possession. How it came there I could not ascertain, as the girl disclaimed all knowledge of it, but did not appear surprised when she found it had been extracted.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. Thornley Stoker, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

MEATH HOSPITAL.

Cases of Urethro- and Vesico-Vaginal Fistula.

(Under the care of Mr. Collis.)

The two following cases, operated upon by Mr. Collis, are fair examples of the success which he claims for his method of procedure. Instead of paring the edges of a vaginal fistula in the usual way previous to bringing them together, Mr. Collis prefers splitting the edges, and turning one of the lips thus formed towards the vagina, whilst he reflects the other towards the bladder or rectum, as the case may be. A quilled suture is then applied, and the vaginal lips are drawn together, with their raw surfaces opposed, the rectal or vesical edges being pushed towards their respective cavities, and their surfaces necessarily closely applied by the same action which draws the rest of the wounded surface into apposition. Mr. Collis states that several advantages accrue from his plan of operating: a larger revivified surface is gained, which must result in a stronger union, and a more complete closure is effected, both because of the larger surfaces which are applied to each other, and by the fact that the urine—if the fistula be vesical—will tend to press the vesical lips of the wound together, exactly in the same way that the lunular portions of the aortic valves are opposed by the blood pressing back against them.

Mr. Collis attributes the success of his operations in some measure to the fact, that he always plugs the vagina with sponge after the operation, and he has found of late considerable benefit from carbolizing the sponge previous to using it.

Mrs. T., æt. twenty-eight, was admitted into the Meath Hospital, September, 1867, suffering from a large urethro-vaginal fistula, situated near the orifice. It resulted from sloughing, following the instrumental delivery of her first child, was of seven months' standing, and was tranverse in direction. It was operated upon in the manner above described, the edges being brought together by four points of quilled suture, and the sponge plug being introduced. The plug and sutures were removed on the fourth day, and the sponge again introduced and allowed to remain for four more days, at the end of which time the fistula had completely closed. The woman was discharged cured, and, having a narrow pelvis, was directed to present herself at hospital, when she should be seven months pregnant, in order to be prematurely delivered. She neglected doing so, and had a very prolonged difficult labour; but although another fistula formed, the cicatrix resulting from the former operation suffered no injury. She died of puerperal fever.

Anne R., æt. thirty, the mother of eight children, was admitted last February, for the relief of a very large irregularly shaped fistulous communication between the bladder and vagina of three months' standing, having its long diameter in the axis of the vagina, and resulting from sloughing following an instrumental labour. Mr. Collis operated in his peculiar method, using five points of quilled suture, and plugging the vagina with carbolized sponge. The sponge and sutures were removed on the fourth day, and a fresh sponge introduced and allowed to remain for four more days. The opening was then found completely closed, and power over the bladder quite regained.

Literature.

LANCEREAUX'S TREATISE ON SYPHILIS. New Sydenham Society.

THE treatise on syphilis before us, by the well known and industrious E. Lancereaux, exhibits in the strongest light the great interest which the subject excites at the present day, claiming, as it does, so much general and scientific attention in order to restrain the almost indefinite and versatile ill effects of disease, not only on the immediate sufferers, but their offspring. The amount of research, labour, and acute observation evidenced by the production of this volume is but consonant with the author's well-known reputation as a syphilographer and observer in this intricate and obscure branch.

The work is most minute and extensive, and cannot fail to arrest the attention of the discreet and thinking practitioner, who may meet with facts reconcilable with no theory, and with variations in the course of the disease which seem to be inexplicable. The latest and most condensed information, founded on a wide range of observation, is placed at his disposal by the judicious course adopted by the Sydenham Society in having this great work translated into English, and thus the most carefully considered conclusions are put before him when sifted and tested by the author's experience. The great connection between the disease in its later stages and the various affections of the internal organs—such as epilepsy, cirrhosis, paralysis, &c.—have of late opened out a new era in the treatment of this disease and its manifestations; and many anomalous facts are now explicable which hitherto escaped observation or were looked on as special diseases. As the author remarks, page 22:—

"Can we be astonished at this when we remember that only within a few years we have recognized the relation between primary and secondary lesions, and the visceral affections previously described and treated under the name of cirrhosis, softening of the brain, &c.?"

We confess that, on the perusal of each work issuing from the press on syphilis and its consequences, we are more and more surprised at the question of the active repression or endeavour to "stamp out" this human plague being left so long undetermined by the executive. Cattle plague, cholera, and fever receive due attention; here is a plague not only destructive to the recipient but to the progeny, yet it is allowed to flourish, because silent in its progress and in its work of deterioration, with what unfortunate result to the community is thus expressed by the author as his experience:—

"*All other things being equal, syphilis rages with greater frequency in proportion as prostitution is less watched over.*"

The author devotes the first sixty pages to a geographical distribution of the disease to show its widespread sway, and quotes Livingstone as to the fact of the interior of Africa being (as yet) free, though this we have lately seen denied by Chapman in his "Travels."

The discussion of the symptoms of the disease is divided into headings, which seem to be most in accordance with a simple method of arrangement:—

The period of incubation.
The period of eruption, or primary lesion.
The period of general eruption, or secondary affections.
The period of gummy products, or tertiary and quaternary lesions.

These stages are fully and ably considered, the leading features displayed, and the pathological changes indicated—a well laid down chart, in fact, of the disease in its various steps to destruction, and from the surface to the interior, is furnished.

A large section of the work is devoted to the consideration of the more subtle and fatal, though less obvious, changes that occur in the internal organs in the latter stages—such as hepatic syphilis, which is copiously treated of, and most instructive cases given in illustration, as well as affections of the kidney, of the brain, the heart, and, in fact, all the internal organs.

We conceive no subject can be more fraught with interest to the practitioner, be he special or general, than this internal syphilization, and the anticipation of such fatal complications should make him the more anxious to cut short the disease in its early course.

False syphilis (p. 95) is handled in an unusually interesting way by the author; be it "simple chancre," "non-infecting," chancreable, &c.; "Was it described or known before or after indurated chancre?" This we conceive a question of great interest, and the writer considers it very difficult to decide. It, no doubt, leaves some part of the question open as to the possible identity in origin of the two varieties.

The proportion of the two varieties (in Paris, at least) is remarkable; thus, of 10,000 chancres—

1,955 are indurated;
8,045 are soft.

As the soft are not followed by constitutional evidences, it would appear, certainly, that the true chancre is more comparatively frequent in this country, as every practitioner knows, unfortunately, how frequent are the cases of constitutional infection.

This volume is full of information, exhaustive in detail, and suggestive as to the rational method of treating the disease in its many phases and under the various disguises it assumes, and displays the author in his merited position as a writer and a philosophical inquirer.

DICTIONNAIRE DE CHIMIE PURE ET APPLIQUEE:

Discours Préliminaire—Histoire des Doctrines Chimiques depuis Lavoisier jusqu' à nos jours. Par AD. WURTZ. L. Hachette et Cie., Paris and London.

The above is supposed to be the introduction to a great French Chemical Dictionary, written somewhat in the style of our Watt's Dictionary. Wurtz's name is a sufficient guarantee of its intrinsic worth, and the historical monograph under notice does not appear before it is wanted. A vein of pardonable national vanity runs through the whole of this introduction. Thus :—"*La chimie est une science Francaise, elle fut constituée par Lavoisier d'immortelle mémoire,*" is rather exaggerated. The Lavoisian theories were constructed upon the works of Black, Cavendish, and Priestley, and had been promulgated previously to Lavoisier by Rea and others; in fact, very few of the theories really enunciated by the French chemist are accepted in the present day—not that we wish for one moment to detract from the glory that deservedly shines round Lavoisier. He was a bright particular star, which shone out distinctly from his collaborators; and the blood of the "*Fermier Général*, No, 5," which was shed on the memorable scaffold, is one of the stains that never wears out of a nation's escutcheon. All these considerations bring us to this conclusion: that it is better to avoid invidious distinctions; for in what nation can we say that chemistry, or any other science, has taken its rise? Germany, Sweden, France, and last (but certainly by no means the least), England, has each had its share. Lavoisier, Dalton, and Berzelius—a Frenchman, an Englishman, and a Swede—have done more for the theory of chemistry than any other individual three men; but this is all that can be said.

In this Histoire des Doctrines, M. Wurtz divides his work into sections:—In 1, Lavoisier and his works are reviewed. 2—is devoted to Dalton and Gay Lussac; their theories and their contemporaries. 3, Berzelius. In 4, Laurent and Gerhardt follows, and he finishes by a review of the science as it at present stands ("*Doctrines Actuelles*").

In this latter part the author undoubtedly does full justice to every one, and it is, in our opinion, the best written portion of the book. He feels at home in describing the labours of his friends, and is particularly happy.

We look forward with considerable interest to the appearance of the other portions of this work. Amongst many good men who have promised to assist in this book, we observe, Kopp, Troost, Willm, and Naquet—the last is a host in himself. Such names make the work invaluable.

◆

Transactions of Societies.

DIALECTICAL SOCIETY.

AT the Dialectical Society of London, two evenings in the months of Feb. and March were occupied by a paper read by Dr. **HARDWICKE**, and by the discussion upon it. The subject was—

PAUPERISM, ITS CAUSES AND MEANS OF PREVENTION.

Dr. Hardwicke was of opinion that, if the Poor-law were well regulated, it would be possible to exact labour from every able-bodied applicant for relief, in return for a frugal meal and a clean bed.

Dr. **STALLARD**, who also spoke, was of a somewhat similar opinion.

Dr. **ROGERS** brought forward some statistics to prove that whenever medical relief is ill paid and neglected, there pauperism abounded.

On the other hand, Mr. **REED** and Mr. **LEVY** contended that the rapid increase of population rendered it impossible to promise the frugal meal and shelter to the able-bodied poor spoken of by Dr. Hardwicke, without destruction to the cause of independent honest labour; and both of these gentlemen, in company with Mr. F. **BOURNE**, Mr. **RIGBY SMITH**, and Mr. **QUELCH**, were of opinion that the only way of getting rid permanently of the enormous amount of pauperism which at present so occupies public attention, was to insist on the paramount importance of persons in this country limiting the number of their children very greatly.

To this argument, Mr. **GEARY** and other gentlemen objected that to advise persons to have small families was likely to lead to immorality.

The Chairman, Dr. **CHARLES DRYSDALE**, responded to this, that Mr. J. S. Mill, who adopted the utilitarian standard of morals, had said that "little advance could be expected in morality until the production of large families was looked upon in the same light as drunkenness, or any other physical excess," and he believed that this assertion of Mr. Mill was quite true. The French had small families, as everyone knew well, and pauperism was certainly not such a glaring evil in France as in this country. He believed that pauperism might disappear entirely if persons would rest content with two or three children, instead of having such large families, as at present. At the same time the present crisis required some extraordinary effort to relieve the misery and overcrowding which was so universal, especially in London.

Dr. **ROBERTS** spoke on the same side of the question, and contended that all slight palliatives did but little good to the pauper class. What was wanted, he contended, was education of that class in habits of forethought and prudence, and above all prudence in the conjugal relations, and they should be advised not to bring into the world more mouths than their industry could support, and not encumber the labour market by overstocking it with a plethora of applicants for wages.

Dr. **HARDWICKE**, in reply, said he did not ask for more for the able-bodied pauper than a minimum of relief—not any relief to enable him to compete with the non-pauper labourer—and, although he agreed with the majority of the speakers in thinking that persons should not have more children than they could support, yet, after saying this, there were a host of details of administration which he had wished to hear discussed by the Society.

Dr. **EDMUNDS** will shortly read a paper on the same subject.

◆

SURGICAL SOCIETY OF IRELAND.

(Continued from page 207.)

PURGATIVES IN STRANGULATED FEMORAL HERNIA.

Mr. **WILLIAM STOKES** said I wish to bring under the notice of the Society, very briefly, the following case of strangulated femoral hernia, which was recently operated on by me in the Richmond Hospital, not only on account of its presenting some features of peculiar interest, but also because I am most anxious to obtain the opinion of members of the Society who have had practical experience in these cases, in reference to an important point in connection with their treatment after operation. The case was one of a young man, æt. twenty-four, by occupation a clerk, who was admitted into the Richmond Hospital on the 21st of last month, having been recommended to me by Dr. Gogarty. The patient stated that he had been ruptured for five years, but up to last August, he never had suffered any inconvenience, having always been able to reduce it without difficulty. On the 23rd of last August, while straining at the water-closet, the hernia came down and became strangulated, and shortly after he was sent to the Richmond Hospital. The patient having been brought fully under the influence of chloroform, I succeeded in reducing the hernia without much difficulty. After this the patient wore a well fitting truss, and suffered no inconvenience until the morning of the 21st of last month, when during a violent fit of coughing the hernia came down and again became strangulated.

I may mention in passing that after reducing the hernia on the first occasion, I felt immediately after a distinct fulness in its site which I rightly considered to be the sac which I had not succeeded in returning.

When admitted into hospital for the second time, he had all the usual signs and symptoms of strangulation, vomiting, hiccough, eructations, pain in groin, tenderness in abdomen, a small and slow pulse, and great anxiety and depression. As I had formerly succeeded in reducing the hernia, and as the strangulation was only of six hours' duration, I anticipated little difficulty in reducing it by the taxis. My anticipations, however, were not to be realized. Taxis was tried with great care, but without producing the slightest effect on the tumour. Directions were then given to put him into a warm bath, to get a full opiate, and an hour subsequently, to get a tobacco enema and tobacco stupe over the abdomen. This treatment had the effect of relieving the pain to a great extent, but had none whatever in diminishing the tension of the tumour. I may mention also that the taxis was tried while the patient was in the hot bath by my clinical clerk, but without success. No effort, therefore, was spared to save the patient from the risk of the operation of herniotomy. At five o'clock in the afternoon I saw the patient again, and as the hernial tumour was as tense as before, and the pain recurred and all the other symptoms had increased in intensity, I operated, and in doing so had the advantage of the able assistance of our President, who kindly came to see the case. As the strangulation was so recent I determined, if possible, to perform the extra-peritoneal operation, though I had some doubts as to my being able to do so from the fact that in this case the hernia was strangulated in an old previously unreduced hernial sac. This constituted the chief peculiarity of this case. The difficulty in reducing the hernia without opening the sac in this case arose from the existence of extensive adhesions between the thickened unreduced hernial sac and the edges of the femoral ring. This I found when I arrived at the sac ; I passed my finger all round its neck, and nowhere could I feel the edge of the ring. I then forcibly introduced a broad-bladed director between the sac and the ring at the upper and inner margin of this ring into the abdomen, breaking down the adhesions that had formed in this situation. The stricture was then divided in the ordinary way, and the intestine, but not the sac, returned. The operation being completed, he got a powerful anodyne draught, after which he fell asleep. The following day he got another opiate. The third day all pain and tenderness having subsided, and the patient feeling inclined to sleep, opium was not considered any longer necessary. I need not enter into the particulars of the daily progress of this case. But this fact is worth mentioning, that there was no motion from the bowels until the seventh day after the operation, which motion was induced, not by the administration of any purgative but by a simple warm water enema. After this the patient had one motion from the bowels regularly every day. I may mention also that the wound healed by the first intention without the adoption of the so-called antiseptic treatment, and the patient was enabled to leave the hospital on the twelfth day after the operation.

Looking at the result obtained in this case, as well as in other cases of strangulated hernia which I operated on during the past years, and in which during the after treatment no purgatives were administered, makes me very desirous of hearing the opinions of some of the members of the Society as to the value of the administration of purgatives in the after-treatment of cases of strangulated hernia. I should be sorry to urge such a revolutionary step in surgical practice as the abandonment of purgatives in these cases, but I think that their utility in the great majority of them may be questioned. In Paris, for example, where the mortality after herniotomy is, I may say, quite unexampled, the routine practice is shortly after the operation to administer an active cathartic draught. I remember during my pupilage having seen several cases in which calomel purgatives were administered after operation. The question, however, which I consider to be of such eminently practical importance is whether, in a local enteritis, which must, to a greater or less extent, be present in all cases of strangulated hernia, we should endeavour to excite by artificial means peristaltic action at an early period, or whether we should abandon such attempts altogether ; or at all events defer them until there is reasonable probability of all congestion and inflammation having entirely subsided. In other words, we should determine whether the principles which guide us in the treatment of cases of ulcerative enteritis with perforation, such as we have occasionally opportunity of observing in typhoid fever, should not also be adopted in the treatment of strangulated hernia after operation.

Professor Hargrave observed that the point referred to by Mr. Stokes was important, but not new. In his early experience it was always the practice to give purgatives if the stomach would bear them. This, however, failed, and as they obtained more pathological knowledge they saw why it had not been successful. They were endeavouring by purgatives to move a paralysed muscle and thereby doing more injury. Now opium was given to afford the muscles time to recover, after which the bowels would quietly take on their natural action. He was of opinion that crude opium would be found more powerful as an anodyne, and would remain more quietly on the stomach than powdered opium. Again, if it was desirable to move the bowels enemata were preferable to purgatives.

Mr. Wharton bore testimony in favour of giving rest to the abdominal contents in cases of strangulated hernia. This was, in fact, the key to success in such operations. In a case under his care constipation continued for a fortnight, and with the best results.

Mr. Collis observed that in the Meath Hospital it was the rule not to give purgatives except there was a special reason for it.

Mr. Croly said a similar line of treatment was adopted in the City of Dublin Hospital. He had operated in eight or nine cases of strangulated femoral hernia, and in one case last session, in which he was assisted by Mr. Stokes, the bowels were not moved for seven or eight days after the operation. The patient complained of pain, and he put off using purgatives believing them to be injurious. In eight or nine days after the operation a fæcal fistula formed, and he was satisfied if any purgative had been given the contents of the bowel would have become extravasated into the peritoneal cavity. In his last hernial operation the patient had a motion before he left the room after the reduction of the hernia.

Dr. Hewitt observed that Dr. Graves recommended the use of opium to allay peristaltic action. The great object was to keep the intestine at rest and give it time to recover. It was important that the hard fæces should not be brought into contact with the softened wall of the bowel. The use of enemata might also be injurious by exciting peristaltic action in the inflamed intestines. Dr. Stokes' father many years ago pointed out the principle which should guide the practitioner in such cases where there was a tendency to rupture, and showed the advantages of large doses of opium. He (Dr. Hewitt) had given as much as twenty-four grains of opium in twenty-four hours without producing narcotism.

Dr. Darby said that in cases of lead colic opium was one of the most valuable remedies. This had been his experience, and Dr. Martin, of Portlaw, who had many cases of the kind to deal with, found it the same. There was one point with regard to the operation which Dr. Stokes had not alluded to, nor, perhaps, had it ever been brought before the Society. Some years ago he saw the case of a young woman who had been operated on for strangulated femoral hernia. She told him she heard the dressers in the hospital say she had been operated on without the sac being opened. She recovered; but she came into hospital again with a tumour as big as his two fists, and the opening into the abdomen was so free that he could put his fingers up and follow the tumour into the abdomen. She was disabled for life. No truss was of any use to her. He drew the inference that in that operation the tendon had been too freely divided ; and shortly afterwards he had an opportunity of operating in a case of femoral hernia. He opened the sac, and—(here Dr. Darby was told by the President that he was not at liberty to depart from the discussion of the point raised by Mr. Stokes.)

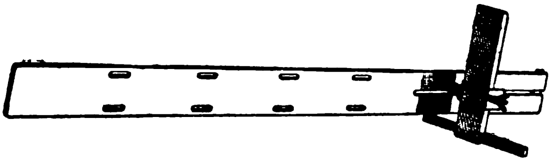
Dr. H. Kennedy said he saw a case in which no inflammation was found in the intestine after an operation for strangulated hernia. The intestine was found to be congested, but without any trace of inflammation. He thought it might be judicious where the intestine was paralysed to try the effect of a weak stream of electricity. He believed with Dr. Hargrave that solid opium was frequently a better preparation than others. He preferred using the watery extract of the drug.

Mr. Richardson said that when he attended Dr. Hutton's clinique in the Richmond Hospital, he frequently spoke against the premature use of purgatives after the operation.

Mr. Stokes, in reply, said that in the last case where he saw Mr. Hutton operate he heard him order ten grains of calomel to be placed on the patient's tongue. He thought it made little matter what preparation of opium was used, provided the desired effect was produced. A solution of muriate of morphia—about thirty or thirty-five drops of the pharmacopœal preparation—was that which he preferred. He thought seven days a long time for a case to go on without a motion from the bowels, and therefore he ordered a warm water enema ; but Dr. Wharton said he had known constipation to last for a fortnight without injurious consequences, and that should render them more patient in looking for a motion from the bowels in these cases. Mr. Collis had stated the rule of practice in the Meath Hospital, namely, not to give purgatives ; but it was not the invariable rule, for he recollected a case in the practice of Mr. Porter, where purgatives were given a short time after the operation—if he mistook not, on the following day. Dr. Darby's observations were most interesting, and he hoped he would draw attention on some future occasion to the modification of the operation. Mr. Croly made reference to an interesting case which he saw him operate on, and which was brought to a most successful conclusion, following the mode of treatment he had found so useful, namely, in giving nothing in the after-treatment but large doses of opium. As to what Dr. Kennedy said of inflammation not existing in the intestine, one could only speak from his own experience; and in all the cases which he (Mr. Stokes) had dissected, he had invariably found evidence of inflammatory action.

SPLINT FOR FRACTURE OF THE THIGH.

Dr. **Darby** exhibited an improved splint which he had adopted in a very bad case of broken leg, where the skin was abraded from both ankles, and where it was important to support the limb without bringing the splint into contact with the injured surfaces.



SIX HUNDRED HEMPSEED CALCULI PASSED BY THE SAME PATIENT IN A FEW MONTHS.

Mr. B. **Wills Richardson** exhibited the prepared section of a calculus which was most skilfully cut for him by Mr. Baker, of Holborn, London, and made the following observations regarding it:—

The specimen under the microscope on the table is a section of a small hempseed calculus, which he believed to be chiefly composed of oxalate of lime. Before the cutting of the calculus by Mr. Baker, it nearly resembled a hempseed in colour, being, however, a little more grey; and it also resembled this seed somewhat in shape, but was not more than about half the size of an ordinary hempseed. In composition, he inferred that it is composed of oxalate of lime with traces of lithic acid, from the fact that the analysis of twenty similar calculi passed by the gentleman who afforded him the specimen had such a chemical composition, being insoluble in acetic acid; soluble to a great extent in dilute nitric acid, which solution, when neutralized with ammonia, became milky white; and all were converted into caustic lime under the action of the blow-pipe.

The patient who passed the calculus, the section of which is before the Society, voided with the urine in the space of a few months upwards of six hundred similar calculi; and many of them, although so minute, are, if he might use the expression, mathematically facetted, so that they were probably lodged in a cyst, which he, unfortunately, was unable to verify, not having had the advantage of a *post-mortem* examination.

The patient suffered occasionally from hematuria, which, while he was under his, Mr. Richardson's observation, rarely lasted more than three or four days, but on each of those occasions a large quantity of blood was discharged.

The prostate was hypertrophied, and the immediate cause of death was melœna.

Before the specimen is examined he should observe that he had not yet been able to satisfy himself as to the nature of the nuclei of the calculi, it was so difficult to grind them, without fracture, sufficiently thin for the purpose. Mr. Baker, however, had recently succeeded in removing one of the nuclei and grinding it so thin that he hoped to identify its structure, and thereby guess the nature of the nuclei of the other specimens, all being apparently counterparts of each other.

The Society then adjourned.

◆

DUBLIN PATHOLOGICAL SOCIETY.

February 13.

A CASE OF DEATH RESULTING FROM THE ACTION OF A GALL-STONE IN ITS TRANSIT FROM THE GALL BLADDER.

Dr. **McSwiney** said the case he had to bring under their notice illustrated one of the dangerous effects, ending with death, that the action of gall-stones in the human gall bladder was capable of producing. Such serious and fatal results as pyemic abscesses, inflammation of the biliary passages, peritonitis, fistulæ, and other grave lesions, had frequently been recorded in the annals of the Pathological Society as happening from this cause. The case now presented illustrated death as resulting from the action of a gall-stone in its transit from the gall bladder into the intestinal tract. The patient from whose body this liver and duodenum were taken, was aged fifty. She entered Jervis street hospital that day week, and had enjoyed good health up to the period her last illness commenced; she suffered occasionally from what she called "windy colic," which was always relieved by a hot application to the abdomen and a warm drink. Nine days previously, shortly after breakfast, she was attacked with a violent pain, which she referred to the right side under the ribs; very soon after severe vomiting came on, and she continued in a condition of great suffering, vomiting everything she took for the next two days, not having consulted any doctor, and relying principally on mustard poultices and other household remedies. Dr. McSwiney saw her on Saturday evening after her admission, and found her jaundiced, though not very much. Her face, hands, and feet were livid and cold, and she was bathed with a cold sweat; there was no pulse to be detected at the wrist, and when he had to determine the circulation he was obliged to do so with the stethoscope over the region of the heart; the tongue was coated with a white fur; her thirst was intense; she vomited everything that was given to her, such as cold water, iced water, brandy and water, chicken broth, &c.; the abdomen was tumid and tympanitic in a remarkable degree; pressure on it, speaking generally, with the fingers, gave no pain; but a space about two or three square inches at the right side, immediately behind the ribs and extending into the epigastric region, was hard, dull on percussion, and intensely painful; this pain was greatly aggravated by movement; in fact, the character of her pain was remarkable; it was of a compound nature, like that which is so generally regarded as the pain that characterizes biliary colic; it consisted of (1) a constant sense of general uneasiness, (2) exquisite local pain, to which was added (3) paroxysmal attacks of intense suffering, alternating with periods of repose. It was quite evident that there was a local circumscribed peritonitis, and it was assumed that there was some obstruction to the peristaltic action, whether of a paralytic or mechanical nature he could not at the time with certainty say; he however suggested that she might be passing gall-stones. She continued getting worse, and died on Monday morning, thirty-six hours after entering hospital, and four days from the first seizure. A *post-mortem* examination was made. She was remarkably fat, and that had, in his opinion, a direct bearing on the nature of the malady. Upon opening the abdomen, the signs of recent peritonitis in a circumscribed area were very easily discovered; the upper surface of the liver was attached to the surrounding parts; the greater omentum, which projected outwards, was attached by lymph to the parts with which it was in contact; the lymph was very recent, and coloured green, the colour of bile, in fact, and it was obvious that there was a considerable quantity of bile poured out which had been mixed with the lymph; the adhesions were easily broken up, and were evidently quite recent. In the stomach there was a quantity of greenish-yellowish coloured fluid, but no solid matter of any kind. It was found that the stomach was adherent by recent attachment to the gall bladder at about the place where the gall ducts unite to form the common duct. Upon breaking up these adhesions, it was found that there was a large pouch at the junction of these ducts which was full of bile; the gall bladder contained a number of polyhedral gall-stones, without a drop of bile. There was, corresponding to the adhesion to the gall duct, an opening into the upper part of the duodenum, which admitted of the introduction of the handle of a scalpel. Tracing down the common duct to its opening in the duodenum, it was found to be considerably enlarged in calibre, and at the extremity, where it normally opened into the duodenum, there was found, firmly impacted, a large gall-stone. This could be recognised on the internal surface of the intestine, and felt with a probe, but he was unable to pass the probe from the intestine into the gall duct, and could not say whether this passage was pervious or not. The condition of the parts was this: the gall bladder was full of gall stones and empty of bile; there was an adhesion between the duodenum and the lower end of the gall-bladder; and at this point there was a large perforation of the intestine; there was an effusion of bile which was evident in the recent lymph by its green colour, and, finally, there was a large gall-stone impacted in the common duct. The sequence of pathological events was doubtful, but he supposed that the large gall-stone which was found at the end of the common duct must have been the initial cause of the changes that had taken place. It may have been in this position for a considerable period prior to death, and the bile may have trickled in small quantities round it into the duodenum, or it may have completely closed the duct, producing an accumulation of bile in the gall-bladder, irritation of the biliary passages, adhesion of the duct to the duodenum, and effusion of bile through the ulcerated opening which was seen, resulting in death.

Mr. Maurice Collis showed

A SPECIMEN OF FIBRINOUS TUMOUR OF THE BREAST,

which occurred in a young married woman of fresh healthy complexion. The disease had only been ten months in arriving at the very formidable size which it presented. The patient was not aware of having been hurt; she did not suffer severe pain, but was greatly distressed by the extreme weight of the tumour. The peculiar features of this class of growth contrasted well with those of encephaloid cancer. In outline it was uniformly globular, not nodulated or lobed; it gave no sense of fluctuation; it was not engrafted on a previously existing scirrhous nodule; it did not in its early stages push aside the proper tissues of the breast, and make for itself a temporary false encysting membrane. Moreover, as compared with encephaloid, it was immensely heavy, very rapid in growth, and infiltrated everything that it came in contact with; still it could be removed and cured in an early stage. Yet, when it once began to implicate the skin and glands, it was much more malignant than cancer. If they examined the structure of encephaloid cancer under the microscpe they would see that it was composed of cells, exceedingly large and delicate, exceedingly feeble and very ready to perish. This tumour was formed of small cells; it contained a large quantity of blood corpuscles, and was very vascular; but the bulk of the tumour consisted of cells, small in size and very firm, about the size and texture of the lymph cells, or the pathological variety of the cells of connective tissue. This tumour was found in various situations; not frequently in the female breast, very frequently in the testicle; and he had seen it in the popliteal space, in bursæ, in the glands, and also connected with the periosteum of the bones. He had one under his treatment in the year 1863, which occurred in the female breast. He had seen the tumour when it was of moderate size, and recommended its removal. She delayed, however, until the tumour could not carry on its own life, and the centre of the tumour sloughed from inability to maintain itself. When the patient came into hospital the tumour was in a state of active gangrene in the centre; a ring of tissue, from an inch to an inch and a half in width, would perish in the day. She was admitted to hospital, and on the third day after her admission he removed the entire breast, and the disease never returned in that situation. This woman married afterwards; her husband indulged in the habit of beating her, and on one occasion he injured the remaining breast, and it became affected by the disease. Mr. Collis saw her when six or seven months pregnant, and on consultation it was deemed advisable not to remove the breast at that time. Ultimately, after she was delivered, the breast arrived at the enormous development depicted in the drawing he now exhibited, and it was removed because of its great weight and the inconvenience it caused her. The disease proved fatal by extension to the lungs. Mr. Collis then showed two drawings, one exhibiting the condition of the breast, and the other showing the condition it was rapidly coming to, for the integument was of a purple colour, and threatening to give way. This tumour now exhibited was removed by the ordinary method. He made the usual circular incision until he came down to the fat underneath the gland, and getting his hand in he thought to tear out the whole of the tumour; however, its brittle character then became evident. He tore it out, leaving a considerable portion adherent to the muscle; ultimately he got all this away. The entire weight of the tumour was 3 lbs. 3 ounces. On making a section it resembled the ordinary encephaloid, except in its extreme weight. It was also much more firm and dense; and when to this they added the rapidity of its growth—that it began in July and attained to this large size in November—he thought they had characteristic proofs, apart from its microscopical character, to differentiate it from medullary cancer. He thought it more malignant than cancer when it arrived at an advanced stage. It implicated the glands, spread to the skin, and would affect every part with which it came in contact. Yet, from its great weight and inconvenience to the patient, he thought they were justified in removing it from the woman, although a permanent cure was not to be expected.

WEDNESDAY, MARCH 17, 1869.

HOSPITAL ADMINISTRATION.

How is it, asks the opener of the debate, in the rooms of the Medical Society of London, a few evenings since, that so many persons flock to hospitals for gratuitous medical assistance, who would feel ashamed to accept alms of any other kind? "Because the profession," adds Mr. Hart, "has accustomed persons of limited means to think that, while honest men, not paupers, must pay for all other necessaries, there is one thing for which they need not pay—the doctor. They must pay for marriage and for burial, for food, clothing, and shelter; they must pay the clergyman and the lawyer." The answer to this question is not very difficult. In the first place, the struggle for existence in the medical profession has of late been so great that, in order to obtain a share of the patronage of the rich, there has been a greater than ordinary competition to secure those hospital appointments without which it is rare that any professional man can hope to succeed. But, beyond even this, there is in medicine, as in learning, and in all the learned professions, as pointed out by Adam Smith, so much that interests the benevolent, and there is so much respect shown by the public to the members of these professions, that they tend, just like the gentle craft of the fisherman, to become ill-paid, and to be invaded by a number of persons, who, being provided with other means of living, are contented to give their professional services gratis. The profession of medicine, too, since the decline in religious beliefs, which marks this epoch, is gradually attracting into its ranks many of those persons whose cast of mind would, in other times of the world's history, have found solace only in deeds of charity and piety. Such, we apprehend, is, in some measure, the account to be given of the deplorable condition of some of the hard-working public practitioners of medicine in this country at present.

Beyond, however, this question, lies the important one of regulation of our hospital system, so as not to do, as many, with much truth, say we are doing, more harm than good, by our charity. There cannot be a doubt that the late modish benevolence, which, in opposition to justice, has so long reigned supreme in British society, has recently tended in a great measure to break down the honest self-dependence and proper pride of our working classes. Mr. Mill has well expressed this in his work on Political Economy, when, in common with all the best writers on that important science, he shows how dangerous it is to relax the checks which keep up the present standard of comfort of the labouring classes. Before the passing of the present poor-law in England, as every one knows, or, alas! ought to know, the allowance system, which supplemented the wages of the poor, had done so much mischief to the labouring classes, that the country was in the greatest danger of being ruined by pauperism. And the very same tale is now being repeated again in the case of medical and other charities. Once accustom the poor and the uneducated labouring class to rely in time of need, without any forethought, on the help of some other person, and you tend to degrade them, and to do far more harm than good. It has, indeed, been found to be compatible with the welfare of the working classes, to afford them, as our present poor-law does, the barest necessaries of life, and thus to ensure to all of us that we need not die of starvation in a civilized country; but, to do more than this is a most serious mistake, and a violation of the rights of the labourer who maintains himself by industry, frugality, and forethought. It is sad that we should be obliged to refer to such well known truths, after such admirable works have been written on this all important subject by Malthus, Chalmers, Whateley, J. S. Mill, and a host of the most distinguished writers on the science of political economy; but, we fear we must say, that our experience of medical men leads us to believe, that a serious study of that science has not formed part of the education of most of us. Hence, in common with the public, benevolence, in our case, often defeats itself by mis-direction. Mr. Matthew Arnold has recently, too, coined a word, "philistine," to express the ideal of the common-place, prosperous Briton, with his large family, his want of appreciation of all that is artistic or systematic, and his conceited contempt for all social combinations which do not exist in his own country. There are, unfortunately, a large number of this type of persons to be found in this country; and this again is one of the chief obstacles in the way of any change in our hospital regulations, or, indeed, in the way of our advance in social science.

For example, who that has observed the whole working of the hospital system in Paris, can doubt that it is greatly superior to the London system? The medical men of Paris, being appointed to their positions by fair and open competition, are, as might be expected, much more universally scientific than our London hospital physicians and surgeons. It is almost impossible, indeed, to be certain that a gentleman now holding any public medical appointment in London is a man of ability, so dubious are the ways by which he is at present obliged to seek for advancement. In Paris he must be up, and continue up, to a certain standard of proficiency in order to compete for the different appointments. This position of our medical men in this country is the key to the condition which they occupy, and to the way in which their public services are rewarded. We believe we may say that, in Paris, there is scarcely any such thing as a honorary medical officer to any hospital; whereas, in London the rule is, that the medical staffs of hospitals are almost unpaid. In many cases, too, years elapse before the hospital physician or surgeon is able to pay his way by means of his practice; and it surely seems absurd that none of the proceeds of the charity should go towards paying the persons, without whose aid such charities could not exist. The consequence of this custom, of course, is to narrow the field of competition to those who are able to live on their own means for some years, until, perchance, practice may arrive, which, of course, limits the number of able competitors, and the public suffers thereby.

The reforms we should suggest in hospital management are very radical. Firstly, there should be, as in Paris, a central office, where all cases which were not urgent should attend, and, if not found by the medical men to be suitable cases for the large hospitals (which ought all to be affiliated), should be at once, as in Paris, rejected.

The large hospitals should be officered by gentlemen, chosen, as in Paris, by open competition, and all should be paid a certain sum, and obliged to attend regularly to their duties. All public charities should be obliged to conform to some regulations, made by a central municipal body, in order to prevent the funds being wasted on persons who could afford to pay; and all accounts should, if possible, be audited by some public functionary. Admissions into hospital should be granted entirely by medical authority, and any other cases, merely appealing as poor people, should be sent to the workhouses. The free system pursued at the Royal Free Hospital, the Metropolitan Free Hospital, and a few others, is far the best for out-patients. When no cases are admitted by Governors' letters, those persons who have some friends do not like to struggle at the doors for admittance along with a number of very poor persons, and hence persons of any means are rarely seen among the out-patients of such hospitals. Had the Bill brought in by Mr. John Stuart Mill been carried, for combining all the districts in London into one federal system, it would have been simple enough to unite all of our hospitals under one government. But the dislike to this measure shown by the members of vestries is probably so great that some time will elapse before this all-important measure can be passed.

◆

HOSPITAL RESTRICTIONS IN THE UNIVERSITY OF DUBLIN.

A MOVEMENT of an influential character, and one in which we heartily sympathise, has been initiated on the part of the medical officers of clinical hospitals in Dublin, and of the candidates for the degrees and licenses of the

University of Dublin. The agitation has for its object the removal of the regulation of the University of Dublin which compels candidates for its qualifications to produce certificates of attendance and lectures from an individual hospital—Sir Patrick Dun's—and thereby practically maintaining for that institution a monopoly of the education of such candidates.

The history of this requirement will not be without general interest, and it will enable our readers to comprehend the allusions to the subject which we may probably be called upon to make.

The School of Physic in Ireland was established in the year 1800, under an endowment from Sir Patrick Dun, and by an Act of Parliament (George III., cap. 84), which provided for the erection of professorships, and the delivery of lectures for the convenience of students, but which in no respect enforced attendance on these lectures as a part of the University curriculum. For thirty-four years the medical degrees of the University were conferred on production of certificates of six courses of lectures from the School of Physic alone (all other educational bodies being excluded with the exception of the University of Edinburgh), together with "two courses of clinical lectures," without restriction as to where those lectures might be delivered. In March, 1834, an order was made by the Provost and Senior Fellows which specifically required "one year's attendance on the practice of Sir Patrick Dun's Hospital, including six months' clinical lectures in that hospital;" and for very many years this continued to be the requisite qualification for all candidates. In process of time other schools sprung up in Dublin, and the University opened its degrees to all comers who might produce a single *Annuus Medicus* in the School of Physic; but the restriction on hospital attendance was not at the same time removed, and has remained to this day as one of the standing regulations of the University. As long as Sir Patrick Dun's retained its original character of being a strictly medical hospital, and as long as the qualifications granted by the University were strictly medical, this restriction attracted little attention; but some years ago the University began to grant surgical qualifications, and about two years ago Sir Patrick Dun's was remodelled, and became a medico-chirurgical hospital, and the existence of the restriction became at once important, not only to the candidates for University qualifications, but to the medical officers of clinical hospitals enjoying, we may say, equal educational capabilities with Sir Patrick Dun's.

We are at a loss to imagine any argument which can be urged in favour of the perpetuation of this unfair monopoly. It is, in the first place, utterly without precedent in connection with any university of the United Kingdom, not one of which require attendance in any individual hospital at all as part of their *Anni Medici*. It cannot, we believe, be suggested that Sir Patrick Dun's Hospital possesses, either in the number of its patients or in any other respect, educational capacity superior to that of other institutions; and it is obviously unjust to the student to compel him to confine his education to any one institution, and impolitic to interpose a hindrance to students from other hospitals in seeking the degrees or licenses of the University. In point of fact, the restriction effects both these results; for although the University nominally requires but one year's attendance at Sir Patrick Dun's, still it enforces on the pupil for that year a payment of twelve guineas, while the subsequent years are only charged respectively nine and six guineas. The effect of such an arrangement is obvious, for, if the candidate *must* take one year and *must* pay twelve guineas for it, it will be, of course, his pecuniary advantage to avail himself of the opportunity afforded him to take the subsequent years at the reduced rates.

We earnestly trust that the authorities of the University and of the hospital will regard the requisition of the medical officers of the "disestablished and disendowed" hospitals from a just and unprejudiced point of view, and at once sweep away a monoply which, we believe, has not the merit even of being politic in a pecuniary sense.

THE WINTER AT PAU AND THE PYRENEES.

(FROM OUR OWN CORRESPONDENT.)

PAU, *March* 10, 1869.

So much has lately appeared in the MEDICAL PRESS AND CIRCULAR respecting the winter resorts of the Mediteranean, and especially Nice, that I think you will be glad to receive a few impressions respecting the equally vaunted climate of Pau as a residence for invalids during the winter. I am well acquainted with the Mediterranean resorts, their value and their defects. I know what true Nice sunshine is, and also the inconveniences of its worst seasons, and am therefore perhaps qualified to contrast them with those to be endured in the Pyrenees. This may perhaps be done by a simple statement of what the past winter has been here. The early part was rainy, and when that word is used those who have been here, and also to Nice, will know what it signifies. It has no analogy at all with the "clouds, then rain, and clouds returning after the rain," so pitifully complained of by your Nice correspondent.

I know Nice well enough to be aware that that phrase proves the winter to have been most favourable there. The climate of Nice is in reality too dry and exciting for many people. It rains too seldom there, and cloudy or rainy days contribute greatly to prevent the overstrung system from snapping. Hence, though not so joyous as the "true Nice weather" (which is a burning, fiery furnace, scorching up the whole frame and exhausting the nervous system by a red glare of perpetual sunshine, accompanied by dry but cold wind—the cause of neuralgia, rheumatism, and all the catalogue of nervous diseases), the cloudy time should be gladly welcomed by every one who wishes to preserve his health. Here, on the contrary, the rainy days are too many, and only add to the depression produced by the so-called sedative air. If it rains here at all, it either pours for hours in torrential floods, preventing all chance of moving outside the house, or it persists, day after day, in Scotch mists or Devonshire drizzle, without a single ray of sunshine to revive the expiring hopes of the unhappy visitor. It is all very well for a man with his own house, or having the best rooms of the best hotel, to heap on the wood and stick to study, or even to light literature, or for younger men to spend the day in a billiard-room, and women to mend the stockings, or embroider or crochet yards of useless stuff. But such a life as that may be led as advantageously in England, without the toil of coming here, the risk of damp beds and fever-infected rooms here or *en route*, and the demoralization which must too often attend a lazy life amongst lazy or delicate people; where the gossip of the *table d'hôte* or the *salon de conversation* usurps the intellectual conversation or useful duties of English domestic life; where receptions, balls, and other desperate displays of toilette, or, too often, want of toilette, fill up the measure of female folly and extravagance, and, by leading invalids to turn night into day, or otherwise, defy all the laws of health, not seldom turn curable into incurable cases, or develope in the young and healthy the seeds of the most intractable diseases.

On the other hand, a bad apartment, or an inferior hotel, makes so much difference that every invalid would be better at home, unless he can secure comfortable accommodation. And this is often very difficult. Not seldom have I known those who say they take cold by the least exposure in England, cross passages in the open air to reach the dining-room, and, after dinner, cross again from the hot rooms, and yet submit to this kind of thing because they were in the hotel where such inconveniences existed. The bed-rooms and sitting-rooms are also both not unfrequently very draugthy. Three windows and two doors is no unusual allowance. In the room where I write there are three double doors and three Venetian windows. None of the six fit very closely. Judge, then, how draught must prevail, how log after log piled on the fire fail to keep up the temperature. The rain drives in at several places. By one window I have had to place a towel to absorb the drops that drive in. How, then, can I keep the place dry? I *ad*mit that some people are more fortunate, but I *sub*mit I have got the best I could, and paid the full price. Again, I acknowledge the same discomforts may be met with at Nice. I have found every evil there just as rampant, and many others I have no time to name. But it will be seen at once that such a state of things is particularly disagreeable in a *rainy* place, and it must be remembered that Pau is particularly rainy. The scourge of Pau is rain. The nuisance of Nice arises from the excessive dryness. Could we divide the qualities of the two places equally, "how happy could one be with either!" But this is impossible, and, being so, I am not sure that too much rain is not worse than none.

But I have forgotten my history. After the damp rainy time at the beginning, there came a lovely calm bright period that lasted several weeks. January and the early part of February were all that could be expected, and went far to make the encomiums passed on the place to some extent justifiable. For those to whom an equable, warm, sedative climate is desirable, who cannot bear too much bracing or stimulating, or have had too much of it, that season must have been propitious. It was cold sometimes, especially at night, but so also, your correspondent says, was Nice. It may be acknowledged, indeed, that the average temperature of Pau is considerably below that of Nice; but then we do not suffer here from the cold wind so admirably described in your columns—and that is a great point. Favourable weather like that is of course appreciated. A wet day, a cloudy day now and then, is thought little of, and the visitors give themselves up to pleasure. Out-door amusements take a prominent place: there is good hunting here, and riding, driving, walking, &c., in good fresh air may do wonders. But afterwards came a long, dreary, rainy time. The latter part of February was worse than Devonshire—cold, damp, miserable. Day after day alternated between drizzle and rain. For half an hour it would clear up a little, and a few would venture out of doors, wearied by their long confinement, and happy to risk wet feet and brave muddy paths; they would, however, be soon driven to shelter by renewed merciless downfall. "The windows of heaven" were indeed opened wide, and seemed never likely to close again. The river rose daily; the low grounds became inundated. Water above, water below, water in the air, now as rain, then as Scotch mist, afterwards a veritable falling vapour; water in the streams, small and great, rushing madly on, carrying everything before it; water in the gardens, parks, fields, meadows, streets, gutters, gullies, rivulets, torrents, pools, puddles, ponds, lakes, inundations, floods—I know not what beside! Water in all directions, till the very pavements seemed to be over-sloppy. No doubt the grand Pyrenees were equally miserable, but they were invisible through the constant stream or vapour, and we might as well not have been in a mountainous district for what we could see. Surely you will have heard of damage done by this excess of water? I waited day after day, in the vain hope of something better, even after I had resolved on the first day clear enough for the journey to run away until the torrential spring rains had abated. At last I rushed forth, amidst a thorough drencher, to that best of friends for discontented travellers, the railway station, and sped to Bayonne, the fine old city where Soult measured strength with Wellington, and the whole country round which is full of memorials of the Peninsular War. Would you hear of the journey? One word describes it—water! Three hours by express through water. The rain abated indeed after I had left Pau half an hour, but not the water. The whole country through which we travelled was inundated. Such floods I have scarcely ever seen, and the mischief done is immense. The Gave, the Nive, the Adour all overflowed, and miles on miles, far as the eye could reach, the whole plain, in fact, seemed a sheet of water; the raised ridge on which the rail ran being in some cases closely approached, and here and there the water rising within a very short distance of the line, the trees a little below being half-way under, or only their tops showing, and many a peasant's house we passed being inundated to the extent of two or three feet, while others had been protected by banks, or were forsaken by the inhabitants.

No wonder, you say, that I complain of the wet at Pau. Yet, is it not a fair question whether a town placed in such a position can be a good health-resort? Besides, when the inconveniences of Nice are so prominently urged, it is but right that those of an alternative climate should be made public. It may yet be a question whether places on our own coast may not—all things considered—compare favourably with any in France. The difference in temperature at Pau is not worth mentioning. The sunshine and exciting atmosphere of Nice, England cannot furnish; but there seems much reason to fear that these properties of the Nice climate are too pronounced, and that they give rise to or aggravate many most serious diseases.

But wind—how about that? For, rainy as it is, Pau has always enjoyed a reputation as particularly free from wind. This it unquestionably is; but even in this respect people require to be set right. Numbers come here with the notion that there is no wind here; they have read enthusiastic descriptions of a place so calm that the leaves scarcely move, and they expect to find it a windless place. Absurd fancy—soon rudely dispelled. It is true that many days here are as calm as possible, but they who say there are no rough winds speak ignorantly or untruthfully. The trees lying by the Gave below uprooted are a proof of that. Those in the place waving to and fro, in majestic indifference to people's fancies and false descriptions, are evidences before my own eyes that too much has been made of this point. I will not relate what I saw and heard on my visit to Bayonne, because a fearful hurricane raged the day after I left Pau, in the discontent I have confessed, and, combined with the floods, did fearful damage. All along the coast, too, the tempest produced its horrors. Pau lies far enough inland to escape the first brush, but, pray, do not believe the storm was unfelt. Far up the mountains, at Bagnère de Bigorre, a diligence was blown over as it stood empty at a door, and the sign of the *lion d'or* was torn and wafted away some distance. I say nothing of chimney-pots and such things. At *St. Jean de Luz*, on the coast near the Spanish frontier, the sea came up into the streets, and has left sand in them two or three feet deep. Of course, houses were flooded and injured. At that same port a hundred yards or more of the sea-wall and the turnpike road were washed away.

I do not describe the effects at Pau, because, as I have said, I went away just before; but if you can believe, after what I have said, there was no storm felt, it would not be worth while to repeat to you the descriptions of those who most love the place, and say there was never anything like it. I admit the distance from the coast and the position would modify a little the wind, and that is all. The wind from the coast is here mostly strong enough. Unfortunately, it nearly always brings rain. Neither the north nor the east winds are so cold as at Nice, or anywhere else in Provence, and the mistral, of course, does not exist. The winds, therefore, are certainly the most favourable part of the climate, and those who suffer at Nice might very well run over here when the spring winds set in. But let them not be disappointed. They are likely to fall in with a spell of wet weather. They may easily drop on a fortnight's rain, and should prepare for it. It is awfully dull after the weeks of clear sunshine, and requires an effort to endure. Still, if the climate is to do them good, it is not necessary to "live out of doors" at first. Escape the wind, that is all; and to do this secure comfortable rooms, if possible, and take to a little repose. The season is Lent. The gaieties will be over, and some quiet should be endurable. When the rain is over the spring at once sets in, in all its glory, and then out-door life can be thoroughly enjoyed. The objection to the above advice I know. It is as easy to keep the house elsewhere. In Provence—no! With such sunshine, whatever the wind, one must go out, and the medical man who tells his patient to stay in deceives himself. In England—yes. For the same reason as here—it will rain. Torquay, Undercliffe, &c., are just as warm as this; but the difficulty is to reach them. From Provence or Italy you can come here without dangerous exposure, by a rail going through a most interesting country. Still, these facts tell much in favour of English resorts, as against all the South of France and Italy. The question of comfort must also be added, and, having thoroughly tried all, I am sometimes half inclined to come round to the opinion of a patient, who says he has tried all foreign climates for fifteen years, and will in future remain in England.

If you wish it, I can on another occasion enter more fully into the subject of this climate. This letter is but a contribution to the information that has appeared in the Medical Press and Circular, and will serve as a warning to those who complain of other places, or are ready to jump at hasty conclusions; but havens of refuge from wind and dust on the one hand, and rain and dulness on the other.

◆

SCOTLAND.

EDINBURGH.

UNIVERSITY—CHAIR OF CHEMISTRY.

We learn from the *Scotsman* that a letter from Professor Lyon Playfair was read at a meeting of the Curators of the University intimating his intention to resign the Chair of Chemistry at the close of the present winter session on 12th of April. It was resolved to defer fixing a day for the election of a successor to Professor Playfair until a further meeting of the Curators, to be held on an early day. Meantime, parties intending to become candidates are requested to forward their applications to the secretary of the Curators, and copies thereof and of relative testimonials to the Curators themselves. We understand that several applications have been already received.

THE WATER QUESTION.

Now that the different Wards have met, it is found that the opinion on this subject is pretty nearly equally divided. Out of the thirteen Wards of the city, seven have decided against the Edinburgh and District Water Bill, and six in its favour. The Bill, however, is thrown out by the House of Lords. "There will now be ample time," says the *Scotsman*, "to discuss, and to consider the whole question, not only of the rival schemes, but of the acquisition or transfer of the water supply to a public trust and the constitution of that trust—matters which the Town Council, in its secret audiences, had prejudged. We are not likely to have for some years so dry a summer as last, and before a like trial of our present supply occurs, the whole matter may be re-arranged on the satisfactory basis of justice to the ratepayers combined with a full supply."

DENTAL DISPENSARY.

The Dental Dispensary has been the means of conferring great benefit upon a large number of patients who for some time would have been unfitted for work, but for the aid afforded them by this Institution. Between four and five thousand cases have been treated during the last twelve months. The report shows a great deficiency in the subscriptions, which amounted only to £33, while the expenses reached £80. An additional effort must be made if the charity is still to be prolonged.

GLASGOW.

A total of £10,700 has been left, we learn from the *Glasgow Herald*, to various institutions by the late Sir James Papillon Jameison, an extensive manufacturer in Glasgow. Among the rest we may mention the following: Royal Infirmary, £1,000; Convalescent Home, £500; Indigent Gentlewoman's Society, House of Shelter for Destitute Females, Glasgow Seaman's Friend Society, Sailors' Home, Blind Asylum, and Deaf and Dumb Asylum, each £250; Lying-in Hospital and the Lock Hospital, £200 each, besides numerous other bequests.

ABERDEEN.

ROYAL INFIRMARY AND LUNATIC ASYLUM.

Lord Provost Nicol presided at a general quarterly court held in the Infirmary Hall on the 8th inst. In the fever hospital, the number of cases at that date were 174, and in the lunatic asylum there were 419 patients. The funds of both institutions were satisfactory, especially those of the Infirmary, which had a surplus of income above expenditure of £1,227 3s. 4d. The surplus of the Lunatic Asylum, after clearing the debt on the erection of Elmhill House, was only £23 10s. 1d. A proposal was made to reconsider, and, where possible, raise the charges for board. The reasons of dissent in Dr. Reith's case as to the practice of homœopathy within the hospital were read and ordered to be recorded. The Monthly Commitee met and considered the question as to the office of pathologist and curator of the Infirmary Museum, which was considered vacant by the appointment of Dr. Beveridge as one of the physicians of the institution. Dr. Roger had applied for the situation, but Dr. Beveridge having sent in a letter stating that in all the principal hospitals of the kingdom the offices of physician were combined, he would have no hesitation in doing both, and giving his best attention to both offices, it was agreed to refer the whole matter to the committee to report. The zeal and assiduity with which Dr. Beveridge has discharged his duties will doubtless have an influence in the decision.

DUNDEE.

ROYAL INFIRMARY.

From the report read at the quarterly court of governors we find that the income of this Infirmary for the nine months ending 28th February last amounted to £2,894; while the expenditure for the same period was £3,037. Large donations and legacies amounting to £1,139 had been received, and it was expected that the revenue up to the 15th May would be quite sufficient to meet all the ordinary expenses which would be incurred up to that date.

◆

Notes on Current Topics.

Relieving Officers, and Medical Orders.

A case of alleged neglect of a very disgraceful character, involving the death of a child, was under the investigation of the deputy-coroner for East Middlesex last week. The deceased was the son of a labourer. The mother deposed that her husband had been out of work for three months. On Saturday, the 20th ult., she applied at the relieving office for an order for her child, who was sick. She asked for a medical order for the doctor. The relieving officer said, "You can get no order, for the child's father is not with you." She applied twice for an order, but she was refused on each occasion. Her husband could not come, for he was out looking for work. In reference to the cause of death, Mr. G. B. Phillips, house-surgeon, deposed that the deceased had died from inflammation of the lungs, which had produced convulsions. The child was suffering from whooping-cough previous to the inflammation of the lungs. It was just such a case where medical care at the earlier stages might have saved life. The jury returned a verdict "That the deceased died from inflammation of the lungs, and that they do not desire to publicly censure the relieving officer, but they request the coroner to write to the Board of Guardians acquainting them with what has occurred, and to state that they (the jury) wish the case to be inquired into." To this complaint the relieving officer responded by declaring that he had no recollection of the applications for relief by the child's mother, but he did not suggest that the woman's story might not be true; on the contrary, he admitted that if the application had been made it would have been treated in the father's absence exactly as the mother complained that it had been. "Medical orders," he said, "were never given when the husband was at work."

We shall be interested to learn by what authority a relieving officer makes it his habit to refuse medical attendance for their children to the sick poor, on the ground that the father is attending to his business elsewhere, and does not see the sense or necessity of his idling a day because his child requires the relief to which he is entitled. We know of no power in relieving officers or guardians to impose conditions which go to frustrate the humane intentions of the Legislature; and if the relieving officer has acted in this matter under the authority of his masters, they are morally guilty by their stupid regulation of the death of this child.

The Milk Fungus.

If we examine under the microscope the superficial layers of cream, we perceive, amongst myriads of globules of milk and of fat, small elongated bodies, accompanied generally by finely punctated masses, such as are found usually in putrefying substances. These are detected in greater numbers at the end of about fifteen or twenty-four hours in summer, and of three days in winter, but *always before the milk manifests any sour taste.* These corpuscles are the spores of a fungus.

This fungus is found not only in milk, but in butter and cheese; even in fresh butter the fungus is met with. The researches of V. Hessling as reported in *Virchow's Archiv*, are of great importance in regard to alimentary hygiene, inasmuch as milk and its products are the aliments of vastly the greatest consumption. It is essential to observe that the fungus exists even when the milk does not show the slightest sour taste. The author believes that many of the disturbances of digestion are attributable to the existence of this fungus. He directs attention to the matter especially in its bearing on the dietary of infants, of which milk is almost the exclusive basis, and in whom intestinal irritation is so frequent and so serious in its degree. The facts published by Dr. Falger, in another number of the *Archiv*, seem to corroborate the opinions of V. Hessling. He has observed that severe intestinal symptoms have at once ceased in infants under the adoption of some very simple precautions, which he details as follows:—

To give the milk as fresh as possible.—In the interval between the milking and the administration of the milk to the child, to keep it in a bottle completely filled and tightly corked so as to exclude the air; and, lastly, to preserve as nearly as possible the natural temperature of the milk as it comes from the cow.

The Gulf Stream.

This is an age of doubt. Everything is in turn called in question. There need, therefore, be no surprise that the existence, or at least the supposed influence, of the Gulf Stream has at length been impugned. Mr. Findley says we are no warmer for it, and all the pretty dissertations of our meteorologists are baseless speculations. These latter will, of course, have something to say in support of their long-cherished belief, and Dr. Carpenter, who has been experimenting, seems to support them, for he found warm and cold currents,—and more too: in the warm region he found that life abounded, while in the cold there was scarcely any indication of vitality. Sir James Ross, in the Southern hemisphere, recorded a regular temperature of 39° Fahr. in all depths in the parallel of 56° 25′ S. lat. Between 59° and 62° N. lat., Dr. Carpenter finds an average of 52° Fahr., with occasional sudden variations attributed to the effects of Arctic currents. There have been accumulated great masses of statistics in many of our south-western towns, as well as in those of the Bay of Biscay, which have been thought to illustrate the genial effects of the Gulf Stream, and which have been held forth as reasons for such places proving favourable winter climates for invalids. The question raised is therefore of vital interest, and the professional gentlemen resident in such places will, we doubt not, direct fresh attention to it. Medical men have always been the prominent authorities on meteorology, and many of them must feel personally interested in the question. Not that any doubt as to the existence of the Gulf Stream could alter the recorded facts as to the warmth of the places to which we have alluded, but the proof that the supposed explanation had been erroneous would open to fresh investigation the causes of the exceptional temperature alluded to.

University of Cambridge.—Natural Science Scholarships.

Competitive examinations in natural science for scholarships are about to be held as follows in the several colleges:—

Downing College (£40 per annum) on Tuesday, March 16th; Clare College (£50 per annum for three and a half years) on Wednesday, 17th March; Trinity College (£80 per annum) on Easter Monday; St. John s College (£50 per annum) Friday, April 9th.

The examinations at Trinity College is open to all undergraduates of Oxford or Cambridge. The examinations at the other colleges are open to all students who have not begun to reside in the University, or who have only recently done so. These scholarships and others are offered each year. Information respecting them may be obtained from the tutors of the respective colleges.

Conversazione at the King's and Queen's College of Physicians in Ireland.

On the 8th inst., Dr. Churchill, the President of the College received his Excellency the Lord-lieutenant, together with a numerous assemblage of the profession, and of distinguished extra-professional persons at a conversazione. The company assembled in the College Hall shortly after eight o'clock, the Censors and Fellows appearing in Academic costume; His Excellency, accompanied by the chief secretary, the surgeons and physicians in ordinary to the Lord-Lieutenant, and other members of His Excellency's staff, arrived about nine o'clock. The tables in the Hall were covered with objects of scientific interest, contributed by Dr. Edward Percival Wright; Dr. Carte, Curator to the Dublin Society; Dr. Barker, Curator to the Royal College of Surgeons, and Dr. Frazer. Some very beautiful microscopic preparations were exhibited, and much interest was excited by a variety of very lifelike glass models of Actiniæ, and a specimen of the cocoa-nut crab.

About ten o'clock the guests of the President partook of supper, and the assembly shortly afterwards broke up.

Official Self-snubbing.

We hear of a very gross official insult conveyed to the medical officers of the Naval Medical Service, which we trust is not to be regarded as the initiation of a similar system for the future.

It seems that two medical officers had incurred the ire of the Lords of the Admiralty. We can hardly credit that the cause is correctly stated, for it reads to us very much like some of the offences of the *peccant nun*, as divulged in the recent storm in the conventual teapot. One navy surgeon had had the temerity in his nosological report to suggest a change of clothing for the crew, for which officiousness he was warned. The second medical officer had appealed to the Admiralty against the order of his commander that he should keep on board his ship alternate nights.

If we can believe that these were really the charges against the medical officers, we need hardly attempt to exaggerate the utter contempt which the action of the department must inspire. But that contempt is exaggerated, if it be possible, by the subsequent course adopted by the authorities, for they not only reprimanded the officers as if they had done something out of rule or culpable, but they sent the charges and verdicts in form of a circular to the commander of each ship, with the request that he would require the medical officers of his ship to read and countersign the paper.

We are not at a loss to say which party, the convict or the judges, are most disgraced by acts like this. A public officer who cannot resist the pleasure of a little-minded slight to his subordinates, ought at least to wait for the colour of a cause, lest he may heroize his victim at the expense of his own very meagre measure of dignity.

Ligature of Great Vessels in Dublin.

The profession in Dublin has been much interested in the progress and result of two capital operations lately performed in Dublin by Mr. Tuffnell, surgeon to the City of Dublin Hospital, and Mr. W. Stokes, surgeon to the Richmond Hospital. Mr. Tuffnell's case was one of ligature of the iliac for aneurism of the common femoral. The limb had attained a circumference of over two feet before the operation. The patient survived for nearly three weeks, but, we regret to learn, died a few days since of pyæmia. On *post-mortem* examination it was ascertained that not the least effort of nature had been made towards occlusion of the artery.

Mr. Stokes' operation was one of ligature of the abdominal aorta close to the bifurcation. The operation was performed with complete success, and we understand that the *post-mortem* examination, for the patient died, indicated a condition of the parts which would have amounted to a cure of the disease if the patient had survived. There was no paralysis of the lower extremities, nor any very strongly-marked decrease in temperature.

We shall, we trust, be in a position to lay full details of these interesting cases before our readers in the Proceedings of the Surgical Society of Ireland.

The Royal Free Hospital, by the will of the late Miss Symes, receives a small legacy towards its funds of £100.

A Greenwich Hospital pension of £50, vacant by the death of J. Osborn, surgeon, on the 25th ult., has been granted from that date to J. Hall, M.D., surgeon.

During the last twelve months the Royal National Lifeboat Institution has saved the lives of 603 persons, and as many as 17,849 since its formation in 1824.

Our Paris correspondent informs us of the severe illness of Sir Joseph Olliffe, a physician and gentleman long held in the highest esteem by all his brethren, who express their intense sympathy and deep concern.

The treasurer of the Lifeboat Institution has lately received intimation from a benevolent lady of her intention to present the sum of £420 for the purchase of a lifeboat to be placed on the coast of Devon or Cornwall.

The second reading of the Pharmacy Act (1868) Amendment Bill comes before the House of Commons as we are at press. The provisions of this Bill are well known to our readers. We may probably touch upon the proposed alterations and extension in our next.

The Lords Commissioners of Her Majesty's Treasury have ordered that 20,000 copies of the work "Nomenclature of Diseases" shall be distributed gratuitously to the registered medical practitioners of the United Kingdom.

Mrs. Jane Hutchinson, relict of Dr. Hutchinson, of Whitehaven, who died some sixty years since, has just met her death by an accident at the advanced age of 100 years. The old lady was in full possession of all her faculties, and up to the time of her accident was in perfect health.

An institution which has for its object the maintenance and education of the orphan children of seamen has lately been established at Liverpool. It is intended to take charge of the girls, and of the boys as well, until they are of proper age to draught off into training ships. £4,000 has been already subscribed.

On the 2nd, 3rd, and 4th of June next, a grand bazaar will be held at the Queen's Concert Rooms, Hanover square, to provide funds for the liquidation of a debt of about £2,000, still owing on the new buildings at the German Hospital, Dalston, and to open, if possible, the last unoccupied ward of twenty-five beds. Her Majesty the Queen, and other members of the royal family, have been graciously pleased to promise their patronage.

By the will of the late Jno. Bairstow, Esq., of Preston, the following, among other munificent bequests, may be recorded :—£19,500 for the erection of a new wing to the infirmary of the House of Recovery at Preston, £5,000 to the Royal Asylum for Idiots at Lancaster, £200 to the Medical Benevolent College, and £300 to the Medical Benevolent Fund, besides other liberal bequests.

We are informed that the council of the Charing Cross Hospital has determined to have a festival dinner in aid of the funds of the hospital at Willis's Rooms on May 12th. It is now nine years since the last festival dinner, and as this valuable institution is in urgent need of pecuniary support, we heartily wish them every success in the proposed undertaking.

The committee of the Devonshire Hospital and Buxton Bath Charity have issued their report for the past year. The number of patients was 1,204, or 74 more than the previous year. There is one peculiarity in this institution, viz., that the patients in the winter are comparatively few, from thirty-five to forty beds being left unoccupied, while in the summer from 100 to 200 have to wait for vacancies. Legacies amounting to upwards of £500 have been received during the year, and his Grace the Duke of Devonshire has given a legal conveyance of the buildings and grounds to the trustees, to be used exclusively for the purpose of the charity.

Correspondence.

THE REUNION OF ENTIRELY SEPARATED PARTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Referring you to my communication entitled "Reunion of an Amputated Finger," which appeared in your impression of the 4th December, 1867, I beg to inform you that, by a remarkable coincidence, the same person has since afforded an additional proof that it is perfectly practicable to reunite, by careful coaptation and warmth, parts that have been completely separated by the knife or any similar instrument.

On Tuesday, the 16th ult., Nelis met with another accident of exactly similar character, half an inch of the index finger of his right hand having been taken off obliquely by the collar-cutter. He came to my house immediately after, carrying the detached part in his left hand. I treated the case precisely as on the former occasion, and with equal success, the nail portion again healing by granulation.

These cases suggest important considerations in favour of "conservative surgery" in every instance where such a course of action is possible.—Yours truly,

Walter Bernard, M.R.C.S.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Although you refuse to insert my letter, you will, I am sure, allow me to correct an important error into which you have fallen. I have never written to any member of the Council of the College of Physicians of Ireland. My letter was sent to each member of the Council of the College of Surgeons of Ireland, asking them to assist in the formation of a Committee of Inquiry on account of the "*misdirection*" of the Adjudicators of the Prize.

Yours obediently,
29, Beaufort street, Chelsea, Edwards Crisp.
Feb. 24, 1869.

You will pardon me for saying that some of your statements respecting the "Carmichael Essays," p. 170, are equally erroneous. Mr. Carmichael directed "that if the essays in 1854 were not thought worthy, that the Council might postpone the grant until 1859, when they had the power of doubling the amount of the prizes." Not a word is said about the power of doubling the amount after this period. Mr. Carmichael directed "that the award should be made by the Council," and not by three jurors chosen by lot, as you report. (See the copy of Mr. Carmichael's will, *Dublin Medical Journal*, 1852.)

[The allusion to the College of *Physicians* of Ireland was a *lapsus pennæ*. Our statements as to Mr. Carmichael's testamentary instructions are substantially correct in every particular.—Ed. M. P. & C.]

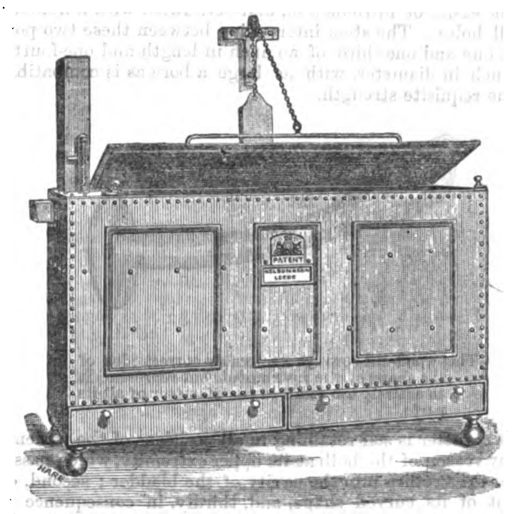
◆

NEW INVENTIONS.

NEW DISINFECTING APPARATUS.

An apparatus has just been brought into public notice by the manufacturers, James Nelson and Co., of Briggate, Leeds, which will bring the advantages of the Disinfecting Chamber, which its expense and dimensions have hitherto rendered unattainable within the reach of small Institutions. The use of heat for eliminating the poison of contagious disease from clothing and bedding and for destroying vermin, has proved more efficient than any of the antiseptics, and in the recent cholera epidemic in Dublin, an elaborate Disinfecting Chamber was erected at a considerable expense, under the supervision of the Medical Officers of Health for the City, and employed with great advantage in the purification of clothes and bedding from the houses of the patients. James Nelson's apparatus appears to fulfil every requirement in a small space and at a reasonable cost, and by its aid we shall hope to see the dangers of transmission of disinfection from the clothes of convalescent patients leaving hospital completedly averted. The illustration appended will give our readers an idea of the apparatus.

NELSON & SONS' DISINFECTING APPARATUS.



The operation is as follows :—Having clothing or other articles requiring purification, the operator places each article carefully over the iron rails of the apparatus, well spread and opened out to the full action of the heat. He then closes the lid, turns on and ignites the gas, and in about twenty minutes he will find the thermometer attached to the apparatus shows a temperature of about 140° outside, which means 200° inside. He then turns off the gas, opens the cold air and flue valves, and in a few minutes the whole of the noxious effluvia will be expelled from the interior, and the clothes can be removed without any offensive effects. The operation can be repeated as often as necessary, but when once the apparatus is warm the result is produced in about ten minutes. Sulphur might be used in the process, but it is not recommended, on account of the lasting disagreeable odour it imparts to clothing, and because dry heat alone is proved to be quite as effective.

Gleanings in Medicine, Surgery, and the Allied Sciences.

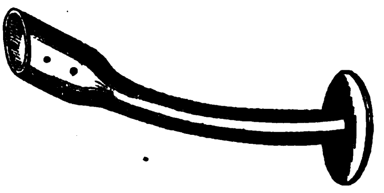
OBSTETRICS.

A NEW METHOD OF CONDUCTING THE AFTER-TREATMENT IN THE OPERATION FOR VESICO-VAGINAL FISTULA.

By Dr. J. Goodman, Louisville, Kentucky.

The cardinal point, in the management of cases of vesico-vaginal fistula, is, in my opinion, *to keep the bladder empty.* When this is effectually done, not only are the lips of the wound prevented from being torn asunder by distension and the muscular activity of the parts subdued, but the organ being collapsed and entirely within the pelvic cavity, is removed from the influence of extraneous agencies, and is very little, if at all, affected by movements of the trunk or lower extremities upon the pelvis. Hence I can see no valid reason for prohibiting all exercise and confining the patient strictly to bed, provided this condition of the bladder can be otherwise maintained.

I believe it would suffice simply to dilate the urethra thoroughly with sponge tents previous to the operation; but, as there is some risk of this giving rise to troublesome or even permanent incontinence of urine, I prefer to use a catheter, and have had one constructed for this purpose, upon the following plan:—It is about two inches in length and slightly bent, to correspond with the shape of the urethra. At the lower or external end there is a button, three-fourths of an inch in diameter, and at the other, or internal, a shouldered cup-shaped enlargement four-tenths of an inch in diameter, bevelled on the convex aspect of the instrument, in order to make it easier of introduction, and perforated with a number of small holes. The stem intervening between these two portions is one and one-third of an inch in length and one-fourth of an inch in diameter, with as large a bore as is compatible with the requisite strength.



This wood-cut conveys a tolerably correct idea of the shape of the instrument, but represents it as entirely too small in the diameter of all its parts.

This catheter is self-retaining in all positions of the patient; first, by reason of the bulb at its upper extremity, which passes beyond the urethra into the cavity of the bladder; second, on account of its curved shape, and, thirdly, in consequence of the button being overlapped and grasped, as it were, by the vulva. It is designed, in accordance with the foregoing views, to be placed in position immediately after the operation, and, as soon as the patient feels able to do so, she is to be permitted to sit up and take moderate exercise *ad libitum.* In this way she will not only be rendered in all respects as comfortable during the after-treatment as she was previously; but her general health and strength will be preserved, and at the expiration of the time usually allotted to the remaining-in of the sutures, if union has not taken place, only a few days need elapse to allow the local swelling and inflammation to subside before another attempt at closure may be made, thus doing away with those long delays of six or eight weeks heretofore considered necessary between successive operations.

Other advantages possessed by this instrument may be enumerated as follows:—Being much shorter than those in general use, it does not irritate the bladder to the same extent, and is not so liable to become obstructed by mucus or blood clots. It is entirely inclosed by the parts, and its temperature is maintained at that of the body, consequently there is comparatively little deposit of saline matter within or upon it, in fact, I have never found it necessary to remove it, on account of incrustations, oftener than once in every seven days, and sometimes it may remain even longer than this. There is no danger of its slipping out of place while the patient is asleep. It may be worn, without causing the slightest uneasiness, for any length of time after the removal of the sutures in a successful operation, in order to prevent undue strain upon the recent cicatrix. Its use does away with all occasion for haste in removing the stitches. Lastly, it is calculated, I believe, to greatly extend the applicability of caustics in the treatment of vesico-vaginal fistulæ. There can be no doubt that contraction and closure of an opening of this kind would be more certainly effected by repeated cauterizations if, in the meanwhile, the bladder was kept empty, and the urine prevented from passing over the healing surfaces; but no one at the present day would entertain the thought of confining a patient to bed, in order to drain off the urine through the urethra by means of an ordinary catheter, while this treatment was being pursued. This instrument, however, will accomplish the same object without inconvenience or the necessity of confinement; and I am strongly persuaded that, used in conjunction with caustics, it would suffice for the relief of fistulæ, even of some magnitude.

DIAGNOSIS OF PARTIAL RUPTURE OF THE UTERUS.

Dr. Hecker remarks that the partial rupture of the substance of the womb without implicating the peritoneal coat is an accident scarcely less serious than when the rupture is complete, but unattended by the alarming symptoms which mark the occurrence of the latter. In general an unexpected fall in the size, with increase in frequency of the pulse, is perhaps the most decisive indication of the occurrence of partial rupture of the uterine walls. Among the local symptoms Dr. Hecker enumerates one nevertheless as of a very negative character, the sudden occurrence of a hæmatocele situated between the walls of the uterus and peritoneum. Dr. H. met with this in two cases. In the first the partial rupture was caused by the presence of a hydrocephalic fœtus; in the second it was the result of medullary carcinoma of the posterior lip of the os uteri. In both cases during labour, the upper wall of the vagina was found to be pressed downwards by a soft elastic tumour. In the first of these cases no examination of the body after death was permitted; but in the second the swelling in the vagina was found to result from an effusion of blood beneath the peritoneum.—*Centralblatt f. d. Medicinisch. Wissenschaften.*

SURGERY.

HERNIA OF THE LIVER.

Dr. G. F. Brickett records a curious case of this in a new-born female child. On preparing to tie the cord, he observed a large tumour protruding through an aperture in the abdominal wall at the site of the umbilicus, extending from the lower edge of sternum to near the pubes. The integuments were dark and excoriated. Dr. B. tied the cord about three inches from the tumour. On his visit three days afterwards, he found hæmorrhage from the tumour, which proved fatal that evening. On examination he found the tumour to be formed of an enormously large misplaced liver, the whole of which was in front, and covering nearly all the contents of the abdomen, being above and anterior to the diaphragm. The right kidney was large; all the other organs healthy and well formed.—*New York Med. Journ.*

AMAUROSIS FROM NEURALGIA OF DENTAL [illegible]

In Zehender's *Klin. Monatsbl. f. Augenheilk*, Dr. Al[illegible] describes a case in which for five weeks the patient had experienced a constantly increasing defect of vision in both eyes, without any change in the appearance of the organs excepting some symptoms of hyperæmia of the pupil, which the ordinary antiphlogistic treatment failed to remove. The patient suffered from neuralgia of the dental nerves connected with carious teeth; upon the extraction of the latter the dental suffering ceased, and soon afterwards the loss of vision was removed; at first on the side corresponding with that from which the decayed teeth were extracted, but after the [illegible] a few days the sight of both eyes became fully restored.

THERAPEUTICS.

TWO SIMPLE APPARATUS FOR THE READY DETECTION OF PHOSPHORUS, ARSENIC, AND ANTIMONY IN MINUTE QUANTITIES FOR THE USE OF PHYSICIANS.

By Dr. D. Müller.

1. The first apparatus consists of a glass flask of about 100 cubit centimetres capacity, closed by a cork which is perforated by a slender glass tube at least 85 centim. high and 3 millimetres wide. Some of the contents of the stomach (or ot her suspected substance) is introduced into the flask, water is added, and the whole boiled. In the dark, the slightest trace of phosphorus will immediately cause a lightning-like, twitching phosphorescence —even if only the hundredth part of the phosphorus of a match be present. 2. The second apparatus consists of a small test tube capable of containing 15 cubit centimetres, half filled with dilute hydrochloric acid, and closed by a caoutchouc stopper. A second stopper of the same material is furnished with a glass tube 3 millimetres wide and about 4 centimetres long, bent at right angles, one end drawn out to a point 1 mm. wide. To test the contents of the stomach, a few pieces of thin sheet zinc are put into the acid, so that a pretty strong evolution of hydrogen takes place, and the test-tube is closed after a few seconds with the stopper bearing the glass tube. The escaping stream of hydrogen is then lighted, and the flame held close to a cold plate of white china. If no spot is produced, the acid and zinc are proved free from arsenic. Some of the gastric contents should then be added, the vessel closed, and after a few seconds' escape of gas, the latter should be lighted and the flame again directed against the cold surface. If a dark spot shows itself it is proven that arsenic or antimony is present in the contents of the stomach tested. The arsenical spot can be easily distinguished from that produced by antimony by external mark. In case of doubt, a solution of chloride of lime or Javelles fluid should be poured over the spot. If the latter is dissolved, it consisted of arsenic ; if not, of antimony.—*Med. Chir. Rundschau*, May, 1868 ; from *Berliner Klin. Wochenschrift.*

Medical News.

Royal College of Surgeons.—The following members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such on the 11th inst., viz. : Messrs. George Redford, Cricklewood, Hendon, diploma of membership dated November 9, 1838 ; Charles Knight, Wellington, New Zealand, April 3, 1840 ; and Gilbert George William Maitland, Her Majesty's Indian Army, October 26, 1841. At this meeting of the Council Professor Richard Partridge, F.R.S., of King's College, was re-admitted a member of the Court of Examiners for a second quinquennial period.

A Great Submontane River.—A very remarkable work, "The Lifted and Subsided Rocks of America and their Influences on Oceanic Currents," by Mr. Catlin, has just been issued by Messrs. Trübner. In it the author announces the discovery of a river under the Rocky Mountains, many times larger than the Mississippi, its course nearly twice the Mississippi's length. Gliding through the clean and vast rocky cellars of the upheaved mountains, without the losses by alluvial absorptions and solar evaporations which diminish valley rivers, it takes along in its course the sinking streams and lakes of the mountains of Mexico, and with them, perhaps by a hundred mouths in its deep bed, debouches unseen into the Caribbean Sea and Gulf of Mexico. The frequent "*Montagnes qui fument*," "*Roches qui tremblent*," and "*Blowing Caves*," which occur in the Rocky Mountain range (he says) indicate submontane cascades, caused by the waters of melting snows, of rains, of glaciers, and a thousand sinking rivers and lakes, which, amongst broken up and angular rocks, are on their way to the ocean level. Through the vast and heated vaults underneath the Andes, I contemplate a similar river, running from the 30th degree of south lattitude to the north, and carrying their overflowing waters also to the Caribbean Sea. The Antilles, now partially sunk in the ocean, are but a chain of mountain tops which, 6,000 years ago, stood up in their grandeur, a part (and, probably, the glory) of the Andes ; and at that date the two mighty submontane rivers, meeting and debouching together into the ocean, east or north of the Antilles, combined with extraordinary volcanic influences, undermined the Antilles chain, which went down in the cataclysm well established in Indian traditions. In this tremendous catastrophe, probably the most stupendous that ever took place on the surface of the globe, the Peninsula of Yucatan, with its splendid Aztec cities, sank, and since has partially risen, leaving the two grand sunken estuaries, the Gulf of Mexico and the Caribbean Sea, into which the two subterranean rivers, from the constant overflow of their vast cisterns under the mountains, now spread their clear and blue waters, heated by the volcanic furnaces they have passed. By the joint influx of these rivers into the Caribbean Sea, its western surface is elevated several feet above the level of the ocean ; and pouring into the Gulf of Mexico, sweeping its western coast, and taking in its way the waters of the Rio del Norte and the Mississippi, this vast flood debouches with them into the Atlantic, at the Florida Cape, and there becomes the "*Gulf Stream*," until now one of the mooted puzzles of the world.

MEDICAL SOCIETY OF LONDON.

On Monday next, March 22nd, at eight o'clock, casual communications. At half-past eight, the discussion on Dr. Jno. Thompson Dickson's paper on "Matter and force, in relation to mental and cerebral phenomena."

NOTICES TO CORRESPONDENTS.

The Science and Practice of Medicine, &c.—We extract the following from the letter of an old and valued supporter on this subject, which, though somewhat trenchant in their application, are nevertheless in some respects but too true. He says :—"I feel quite sure that the management of a medical journal can at times be no sinecure. From my knowledge and past experience of men in our profession, the great amount of nonsense constantly written by them, without in the slightest degree advancing us a step in true or useful knowledge of the *sciences* or *practice of medicine*, that I get weary of contending with them, and so long as we remain ignorant of the manner in which vital, electrical, and chemical forces are associated, is it not premature to expect any satisfactory explanation of the processes of life? You also find from the remarks made in many numbers of your valuable journal during the last few months, by some of the most honest and truthful members of our profession, that our present knowledge of therapeutics, as hinted before in my note, is very unsatisfactory at this time, and it is high time we set about investigating the relations between the pathological condition of internal organs, and the action of *medicinal* substances ; as also the dependence of the secondary or therapeutical action of such substances on their primary or physiological effects, and the various lesions to which such internal organs are liable, that for the present too much has to be left to conjecture, and in the meantime *Nature* is very bountiful in lending her aid to whatever rational plans may be adopted."

Dr. Vesey.—In our next.

Mr. Henry Pitman (Manchester).—Your letter shall appear in our next

Dr. French (Raipore, Bombay).—Is thanked for his communication, those portions of his letter needing attention will not be neglected. The letter is now in the proper department, from which Dr. French will doubtless be shortly favoured with the document he requires.

Dr. Kinkead.—Your letter will probably be inserted on the 24th inst.

"Iodide of Ammonia in Diseases of the Glandular System," by J. Waring-Curran, Manchester, received.

"Remarks on Etherised Cod-liver Oil," by Balthazar W. Foster, Professor of Medicine in Queen's College, Birmingham, to hand.

Dr, More Madden.—We regret that pressure upon our space during the past few weeks has prevented the publication of your own and several other valuable communications. Our usual plan is to publish each paper in the order it is received, the shorter contributions generally having preference. Proof of a "Case of Psoas Abscess" shall be sent you without further delay.

Our correspondent, whose letter appeared in our last issue, is probably by this time aware that the "well-known practitioner of cutaneous medicine and surgery" referred to in the *Lancet*, of Feb. 20th, is Mr. Erasmus Wilson, and that his offer of £5,000 and a fine collection of casts to the Royal College of Surgeons, to found a professorship of cutaneous pathology, was received and referred to a committee for the settlement of details. The offer was made irrespective of any conditions.

BOOKS, PAMPHLETS, &c., RECEIVED.

The Surgical Treatment of the Diseases of Infancy and Childhood. By T. Holmes, M.A., Cantab. London : Longmans, Green & Co.

A Manual of Therapeutics. By Richard Hughes, L.R.C.P., M.R.C.S. London : Henry Turner, Fleet street.

Medical Anatomy (coloured plates). By Francis Sibson, M.D., F.R.S. London : John Churchill and Sons.

APPOINTMENT

M'Laurin, W., M.P., C.M.—Resident House-surgeon to the Greenock Infirmary, vice W. B. Hunter, M.D., whose term of office has expired.

Deaths.

Barham.—On the 3rd inst., T. F. Barham, M.B., of Newton Abbot, Devon, aged 74.

Jones.—On the 8th inst., John D. Jones, M.D., of Queen's road, Dalston aged 57.

Lye.—On the 8th inst., Horatio Lye, M.R.C.S.E., late Surgeon H.E.I.Co.'s Service, of Hayle, Cornwall, aged 83.

Advertisements.

THE NOVA SCOTIA GIANTESS, MISS ANNA SWAN, 8 feet high, 20 years of age, respectfully announces that she holds Levees to crowded audiences daily, at the EGYPTIAN HALL, PICCADILLY, from Half-past Two until Half-past Four, and from Half-past Six until Nine. Admission One Shilling.

THE SIAMESE TWINS AND THE BEAUTIFUL CIRCASSIAN LADY continue to attract crowded audiences at the EGYPTIAN HALL, PICCADILLY. Notwithstanding the great sensation they have created in the Metropolis, they must shortly leave London. Receptions daily from Half-past Two until Half-past Four, and from Half-past Six until Nine. Admission, One Shilling.

THE LONDON SURGICAL HOME,

FOR Diseases and Accidents of Women; for the Reception of Gentlewomen and Females of respectability, upon a weekly payment, under the sole management of Mr. Baker Brown.

The Private Medical Attendants of the patients are invited to visit them, and to meet in consultation before treatment.

Full particulars can be obtained on application to the Lady Superintendent, 136 Harley street, near Regent's park, London.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

FIRST OR PRIMARY PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination will commence on Tuesday, April 6th. Students are admitted to this Examination after the termination of the Second Winter Session of Professional Study at a recognised Medical School.

SECOND or PASS EXAMINATION for the LICENCE.—The next Examination will commence on Tuesday, April 13th. Gentlemen who have completed four years of Professional Study according to the College Regulations are eligible for admission to this Examination.

Registered Medical Practitioners, qualified before January, 1861, are admitted to Examination under special Bye-law.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-laws are to be left at the same time.

H. A. PITMAN, M.D., Registrar.

Pallmall East, 1869.

THE ANTHROPOLOGICAL SOCIETY OF LONDON.

4 ST. MARTIN'S PLACE, TRAFALGAR SQUARE.

ESTABLISHED IN 1863

FOR THE PROMOTION OF THE SCIENCE OF MAN BY THE ACCUMULATION OF FACTS BEARING ON HIS PAST HISTORY AND PRESENT STATE IN ALL PARTS OF THE WORLD.

President for 1869—John Beddoe, Esq., M.D.

Gentlemen desirous of being admitted Fellows, may obtain forms and information on application to

J. FRED. COLLINGWOOD,
Secretary.

LIVERPOOL INFIRMARY FOR CHILDREN.

WANTED, A HOUSE SURGEON (unmarried) for the above Institution, at a salary of £60 per annum, with board, washing, and lodging. No person is eligible who is not on the Medical Register of Great Britain, and who does not possess at least one Medical and one Surgical Diploma, License, or Degree recognised by the Medical Council. Candidates are requested to send in their Testimonials, addressed to the Hon. Secretary, on or before Monday, the 22nd inst. Selected Candidates will receive notice requiring their attendance.

JOHN CALDER, Hon. Sec.

Liverpool, March 10th, 1869.

COUNTY AND CITY OF CORK MEDICAL PROTECTIVE ASSOCIATION.

THE ANNUAL MEETING will be held at the ROYAL CORK INSTITUTION, on THURSDAY, 18th inst., when the Chair will be taken at Four o'clock. Members will dine at Seven o'clock on the same evening, Meeting and Dinner being open to the whole Profession.

By Order, CHARLES ARMSTRONG,
Hon. Sec.

March 1st, 1869.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby given, that the next PRELIMINARY EXAMINATION will be held on WEDNESDAY, the 21st DAY of APRIL next, at 2 o'CLOCK p.m.

The following are the subjects upon which the Candidates will be examined, viz.:—The English Language, including Grammar and Composition; Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations; Geometry, First two books of Euclid; Latin and Greek, including Translation and Grammar.

By order,
JOHN BRENNAN, Registrar.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE,
50, Lincoln's-inn-fields, W.C.

MR. J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. (King's Coll.), has always upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements and no expense incurred (except in special cases) unless a negotiation be completed.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

A prompt and just system secured a large measure of success to the General Partnership and Commercial Agency Business formerly conducted by him at his City offices; this has for some years been transferred to Lincoln's-inn-fields, and he has invariably adopted the same equitable policy in the more professional matters placed in his hands. Thus his experience in the management of large commercial undertakings, combined with his medical, scientific, and literary acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on matters of dispute between professional men, Mr. Langley has had great experience, and he can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation, and in which his awards have been made rules of her Majesty's Courts at Westminster.

Mr. Langley can also refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

HYDROPATHIC ESTABLISHMENT.—PARTNER WANTED.—The locality is beautiful and well frequented by visitors. There is a general practice connected with the Institution which has been established for 20 years. New premises are in course of erection, and the practice can be largely increased. The incomer must have at least £1,000 at his command. Address X 497, care of Mr. Langley, as above.

PARTNERSHIP.—£800 a year for negotiation, the two-thirds share in a well established practice in a seaport town. The senior to retire at the end of 5 years. The practice has been established 22 years. Appointments return £200 a year. Liberal terms would be conceded to a suitable gentleman, but no one need apply who has not at least £500 at command. Address X 495, care of Mr. Langley, as above.

SEA SIDE PRACTICE for TRANSFER; situate in a picturesque and improving locality, where there is great scope for increase. Present income £350 a year; appointments £150. Address X 502, Mr. Langley, as above.

LONDON, W., PARTNERSHIP.—For TRANSFER the half share of a good suburban PRACTICE, at present realising £1,000 a year, and capable of great increase by the co-operation of a well-qualified gentleman of good address. Premium £1,000. Address X 511, care of Mr. Langley, as above.

EXCELLENT NUCLEUS.—The opportunity of SUCCESSION on very easy terms to a seaside PRACTICE is open to a suitable gentleman, with double qualifications. The present incumbent being unmarried and possessing private means has not pushed the PRACTICE which can be increased to an almost unlimited amount. Present income £200. No midwifery under two guineas. Pleasant house. Rent £35. Address X 510, care of Mr. Langley, as above.

CHANNEL ISLANDS.—For TRANSFER, a well established family PRACTICE, with good appointments. Income between £400 and £500 a year. No midwifery under £1 1s. The house is situate in the most fashionable part of a good town; it contains 13 rooms, stable, and coach house, and commands a fine sea view. Rent £43, no taxes. Family reasons induce the vendor to reside in England. Address X 507, care of Mr. Langley, as above.

GOOD COUNTRY PRACTICE for TRANSFER.—Income upwards of £400. Appointments £90. Patients—farmers and tradespeople. Hunting, shooting, and fishing, in the locality. Railway communication convenient. House with stable, garden, and every convenience. Rent £24. Half premium may be paid by instalments. Terms a year's purchase. Address X 506, care of Mr. Langley, as above.

UNOPPOSED COUNTRY PRACTICE.—In a small town, with excellent neighbourhood, an old established PRACTICE for TRANSFER. Average income £543 a year. Appointments about £40. No opposition within 4½ miles. Patients of a good class. About 20 midwifery cases in a year. House detached, with orchard and garden, can be rented or purchased, being the vendors own freehold. Premium £500. Half in cash and remainder at the end of introduction. Address X 427, care of Mr. Langley, as above.

MR. LANGLEY'S QUARTERLY LIST OF SELECTED PRACTICES and PARTNERSHIPS for the New Year was ready on Friday, January 1st. Free by post for two stamps, from the Professional Agency, as above.

Now ready, Second Edition, with considerable additions,

ADVICE ON BUYING OR SELLING MEDICAL PRACTICES, PARTNERSHIPS, &c. By J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c.—Free by post for seven stamps.

REMARKS ON ETHERISED COD-LIVER OIL.

By Balthazar W. Foster, M.D., M.R.C.P. (Lond.),

Professor of Medicine in Queen's College and Physician to the General Hospital, Birmingham.

Any improvement in the administration of cod-liver oil must necessarily be important, for the Profession has scarcely any remedy so potent for good in many cases, and yet oftentimes so objectionable to the very patients for whom its use is most essential. I have, therefore, thought it desirable to make a few remarks in the Medical Press and Circular on a preparation of cod-liver oil which I have now used for some time past with much success, and which, in my experience, overcomes the obstacles to the use of the ordinary oil. The chief of these obstacles is the difficulty with which the remedy is borne by many consumptive patients; a difficulty which arises in part from the nauseous flavour of the oil, but more especially from the defective assimilation of all fatty food, which characterises so large a proportion of these patients. The abhorrence of all fat, which so many consumptives express, makes it of very little use to order the remedy without first taking means to ensure, not only its tolerance, but what is much more important, its digestion. This has been generally insisted on in theory, but I am afraid, nevertheless, very generally neglected in practice, and cod-liver oil has been prescribed for years, and is still being prescribed, without due reference to the power of the patients to assimilate it.

The attention of prescribers has been too much directed to masking the nauseous flavour—to tricking the stomach into accepting the drug, and too little to the treatment of that morbid condition of the digestive fluids, of which the horror of fatty food is simply the outward expression. In phthisis, more than in any other disease, do we meet with this inability to digest fatty articles of diet, as a symptom demanding our attention, and often persisting in spite of our most elaborate therapeutical formulæ. A sense of the unsatisfactory resources at my command wherewith to combat this symptom long ago impressed itself on me, and made me dissatisfied with the crude therapeutics which prescribes cod-liver oil as the routine remedy for all consumptives, without any sufficient preliminary inquiry into their ability to digest it.

The reform of this practice appeared to require a careful search into our knowledge of the digestion of fat, and a further search for some agent capable of influencing the secretions of those glands which are specially devoted to assimilating fatty food. For a long time it has been known that the digestion of fatty food is performed in the upper part of the small intestines, and that the secretions of the pancreas and duodenal glands, which are poured forth to meet the food as it leaves the stomach have a special transforming power over the fatty constituents of our diet. But strangely enough we have hitherto made little use of these results of experimental physiology. Even the very experiments which so clearly established the relation of the pancreatic functions to the digestion of fat have been studied over and over again, but the important clue therein contained as often overlooked. In the same pages in which Claude Bernard relates his views of the action of pancreatic juice, he tells us of the means he used to augment the secretion of the pancreas, and thereby discloses the physiological action of a drug of which the therapeutical value can scarcely be overrated. This drug is ether. In one of my lectures on "The Nature, Causes, and Treatment of Dyspepsia," published in this Journal in 1866, I referred to this subject when speaking of the causes of intestinal dyspepsia, and in a recently published paper* I have quoted a number of passages from Claude Bernard's works, which refer to the physiological action of ether. In the present instance I will quote another passage from Bernard, in which he describes the experimental demonstration of the fact. Speaking of the effects of the administration of ether, he says,* "I have accordingly been able to avail myself of this procedure to obtain pancreatic juice. Normally this fluid discharges by drops more or less infrequent, but when a little ether is given to an animal having a pancreatic fistula, this discharge is seen to become more abundant without the secreted liquid having lost any of its physico-chemical characters. Here is a rabbit upon which we will show you this increased secretion under the influence of ether. By the procedure already described we lay bare the pancreatic duct, and into it we introduce a small silver tube; you perceive the intestines of the animal red, very vascular, and containing ether in vapour; the animal has received into its stomach 5 cc., which were immediately vaporised and diffused in the stomach and intestines. The animal is lying on its left side, and is in a state of complete anæsthesia: this effect is very easily obtained by giving ether by the stomach in the case of rabbits, but with more difficulty in the case of dogs, as you know. The tube which we have introduced into the pancreatic duct evidently gives passage to a very active flow of pancreatic juice, while in the ordinary conditions the liquid flows drop by drop with much less frequency. I would remind you again that when the pancreatic juice flows in greater abundance it becomes more liquid and more watery, a condition which is not a consequence of the administration of ether, but one which occurs in the physiological state. Ether we have seen increases the absorption of fatty matters, which it places in a state of very fine division, and in contact with a more abundant secretion of pancreatic juice. In this way it produces a very marked white injection of the lacteals. Ether enables us to demonstrate on the living animal that the pancreatic juice alone emulsifies fat. A demonstration difficult in the ordinary conditions of digestion, on account of the time it requires and the sources of error to which the pathological state caused by the operation may give rise. If two rabbits are taken as young as possible, and then the pancreatic duct tied in one of them, and into the stomachs of both a solution of fat in ether be injected, there will be seen, on afterwards opening these animals together, that in the rabbit whose pancreatic duct was tied the lacteals contain only transparent lymph, whilst in the other rabbit they are filled with a milky lymph."

---

* Vide *British Medical Journal*, Nov. 21 and 28, 1868.

Guided by the knowledge of the physiological action of ether thus elucidated by the labours of our most brilliant experimentalist, I have for some years studied the therapeutic action of the drug, and my convictions have daily grown stronger that we have in ether a most potent remedy for promoting the digestion and absorption of fatty food and cod-liver oil. Over and over again I have by this means been able to induce a stomach once intolerant of all fat to accept good naturedly full doses of cod-liver oil, and after a time—sometimes weeks, sometimes months—to relish it without any ether. At first the ether was given in a mixture a short time before the administration of the cod-liver oil, in some few cases the ether mixture was given after the oil, and this mode of using it is still preferred by some practitioners. For my own part, I have for some time past discontinued in the majority of my cases the plan of giving ether separately, and adopted a mixture of ether and oil, which is now generally known as "Etherised Cod-Liver Oil." To every two drachms of cod-liver oil ten, fifteen, or twenty minims of ether are added, according to the strength required. The *Æther purus* of the British Pharmacopœia is used in preference to any other preparation, on account of the clear mixture which is obtained. When ether containing alcohol and water is used the oil is rendered muddy. Sometimes a greater proportion of ether than the twenty minims to the two drachms (the ordinary dose) may be given, with the effect of making a still more palatable compound. I have now treated a large number of phthisical patients with this oil, and the results have been most gratifying. In my paper in the *British Medical Journal* I have given an analysis of fifty cases. Of these, 40 per cent. improved, 32 per cent. remained stationary, and only 28 per cent. became worse under treatment. These patients were carefully weighed from week to week, and the improvement in general symptoms and physical signs only accepted as satisfactory when confirmed by an increase of weight. Six cases at least deserve to be considered as cases of arrested phthisis. If the amelioration in physical signs and general symptoms had been considered in these cases, as satisfactory evidence of improvement without reference to the increase in weight, the 32 per cent. recorded as stationary might have been added to the 40 per cent. registered as improved. And looking back on these cases after the lapse and with the additional experience of another year, I believe that the statement that 72 per cent. of the cases treated by ether and cod-liver oil improved, would not be an exaggeration.

Now, in these cases, and in a great many more which I have since observed, the good results were, I believe, attributable to the improved state of general nutrition following the digestion of the cod-liver oil. In a great number of cases the administration of cod-liver oil to phthisical patients is comparatively useless, for the digestive organs are not in a state to transform and assimilate the remedy. The nausea and sickness which it occasions, as well as the absence of an improvement in general nutrition, are proofs of this. In some consumptive patients, on the other hand, but they are much fewer in number, the power of digesting fatty food is not so much impaired. These cases are for the most part more chronic in their course and more amenable to treatment. It is to the former class that etherised cod-liver oil is a remedy of value, for it is frequently borne when ordinary oil has been over and over again rejected, and the improvement in the general symptoms which follows its use in these cases is most marked. Not many days since, in visiting my patients in the General Hospital, I noticed that the shirt of a strumous child, for whom I had ordered cod-liver oil on admission a few days previously, was badly stained by the remedy. I inquired if the oil had been spilled, but learned from the nurse's reply that the child always rejected a greater part of the oil. This had not been mentioned to me before as the nurse thought it well to persevere with the drug. The ordinary oil was changed for the same dose of etherised oil, and with the best effects. No longer was the oil rejected, the very first dose was retained, and day after day the child's appearance improved, and his appetite increased. Such cases constantly occur among my out-patients, and when the etherised oil does not at once obtain a favourable reception from the stomach, a few doses of a mixture containing ether will almost invariably give the patient the power of taking the oil without any feeling of discomfort. That ether has the power of removing the great obstacle to the beneficial use of cod-liver oil there can, I think, be little doubt, and in my experience, and in the experience of many others who have used the remedy largely, the etherised oil is much less nauseous than the ordinary oil. Some persons have, however, a great repugnance to the taste and smell of ether, and to these the etherised oil is very distasteful. Sometimes the addition of a minim or two of chloroform will counteract this. In other cases I have observed a fact to which Professor Cuming, of Belfast, has also called my attention—viz., that many persons who can take the ordinary cod-liver oil very well cannot take the etherised form. This may, I believe, be accounted for in some cases by an antipathy to the ether, and in others it is very much what we might expect to occur in persons whose digestive organs require no stimulation, and whose powers of assimilating fat are already sufficient to enable them to take the cod-liver oil in its natural state. To such cases I now never order any but plain oil, and if I find after they have been under observation for some time that the improvement is not satisfactory, a little ether added to any mixture the patient may be taking will often prove beneficial without being objectionable.

---

* "Leçons sur les Effets des Substances Toxiques et Médicamenteuses," p. 427.

I cannot close these remarks without alluding to the confirmatory evidence of the therapeutical action of ether in promoting the assimilation of fat contained in Dr. Ramskill's important observations on the use of olive oil as a remedy. From many observers I have received strong assurances of the advantages of the combination I have recommended. I will only quote the words of one whose high position as a physiologist and reputation as a clinical observer give special value to his words. I refer to Dr. Mapother, of Dublin, who writes as follows:—"Since I had the advantage of hearing your paper at Oxford I have given etherised cod-liver oil in about fifteen cases, chiefly those of strumous and rheumatic diseases of bone. It is far easier to take than the oil alone: the ether acts as a good stimulant, and I think it fattens the patient more surely, for your views as to the increased pancreatic flow and improved emulsification of fat are sound." I now ask the readers of this Journal to assist me in the further elucidation of the therapeutic value of ether and etherised cod-liver oil in the treatment of pulmonary consumption and other maladies characterised by inability to digest fatty food.

EPITHELIAL CANCER OF THE PENIS—

AMPUTATION OF THE ENTIRE ORGAN — WEIGHT FIVE OUNCES — DISEASE OF TWELVE MONTHS' STANDING — RECOVERY, WITH POWER TO EXPEL THE URINE TEN FEET—SUBSEQUENT STRICTURE.

By John Stuart Vesey, M.D., L. & F.R.C.S.I.,
Medical Officer to Magherafelt Fever Hospital, Workhouse, &c.

Joseph P——, æt. seventy-two, a weaver, admitted 19th May, 1868, into the Magherafelt Union Infirmary; states that he always enjoyed good health up to the time of his present malady. He is married, and the father of ten children, four of whom died young; the remaining six are in good health. His father and mother lived to the age of seventy-six; neither they nor any of his other relatives as far as he is aware, ever suffered from malignant disease. He never had venereal in any form. The prepuce was congenitally very long, and completely covered the glans penis.

About a year ago he first noticed a small tumour, the size of a pea, beneath or in the prepuce on the left side. This speedily enlarged, became red and painful, and finally burst, when about the size of a marble, discharging a quantity of purulent matter mixed with blood. The prepuce was in a state of phymosis. In the course of a month a similar suppuration took place on the right side, leaving a bridge of healthy skin on the dorsum of the organ. Ulceration spread from both openings, and in four or five weeks the connecting bridge of skin was destroyed, leaving an opening through which the glans penis slipped, while the prepuce fell down like a pendulous pouch beneath the frænum. From that date till the present the ulceration gradually extended on all sides, implicating almost the entire organ. He occasionally suffered a burning darting pain, but in spite of all kept to his work until within a fortnight of admission, never having consulted any medical man. He has had hæmorrhage at intervals, and this has given him temporary relief.

On admission, his general health appears to have suffered little; his appetite is good; his bowels are regular, and he sleeps pretty well. The penis bears a very characteristic appearance, resembling an irregular nodulated mass of fungoid growths of a reddish hue, the intervals between them being filled with pus and a thick white viscid exudation. On a front view, the penis appears bicephalous; the glans on the left side, while the remainder of the prepuce is on the right and rather below. An ordinary observer, standing a few yards off, could scarcely tell which was the glans. The latter organ and the prepuce are very much indurated, but have in a degree resisted the ulcerative process. The ulceration next the pubis is bounded by a border of dark red skin, approaching nearer to the pubis on the left side than on the right. When the penis is well pulled forward there is found to be only three-quarters of an inch at the narrowest part between the dark red skin bounding the ulceration and the pubis. The extent of the diseased mass from before backwards is three and a half inches, and from side to side three inches, its circumference at the broadest part of ulceration being seven and three-quarter inches. The inguinal glands (three on the right side and two on the left) are only slightly affected, more, I considered, from simple irritation than by reason of any specific poisoning.

The man was anxious and pressing for operation, more so, I confess, than I was; however, after due consideration, I acceded to his wishes.

Operation, May 26, 1868.—There was a systolic bruit audible in the heart, together with some irregularity of action; so that it was decided not to administer chloroform. The penis being put on the stretch, a very narrow tape was tied round it, as tight as possible, close to the pubis. A circular incision was then made through the skin, as nearly as possible to the tape, down to the corpora cavernosa. The urethra was then cut through, about one-sixth of an inch in front of the superficial incision, and dissected back to its level; the knife was then turned up, and the operation was completed by a rapid sweep of the instrument. He bore the operation very well. There being no hæmorrhage owing to the pressure of the tape, there was delay and difficulty in finding the mouths of the severed arteries, four of which were tied. This was scarcely done when the corpora cavernosa retracted under the pelvis, leaving the tape firm round the remaining skin. This ligature, being of no further use, was then removed. With considerable difficulty the urethra was caught and pulled forward by a pair of forceps from under the pubis. Four cross cuts were then made in it with a sharp scissors, and each point was attached to the external skin by a very fine needle and silk. The stump (if that could be called a stump which was rather behind the level of the pubis) was dressed with lint and cold water. The cancerous mass weighed five ounces. The case went on most favourably. The ligatures came away the first week, and the wound healed kindly, perfect rest in bed being enjoined.

On being asked how he made water, he answered "splendid;" and on one occasion he said he could urinate across two of the tables that happened to stand in the ward. This I had difficulty in believing, as I recollected the words of Mr. Erichsen in treating of this subject. In page 1198 of his valuable work on the "Science and Art of Surgery" that gentleman says:—"After amputation of the penis, the urine will not be projected forward, but always passes directly downward between the legs," &c., &c. I was curious to see if my patient were an exception to the rule so strongly laid down by Mr. Erichsen, and I found he was; for on the very first opportunity I got him to empty the bladder in my presence, and before two patients who were in the ward with us at the time. The organ was only half full, nevertheless he made water in a round stream, and propelled it exactly ten measured feet straight before him. That day he insisted on leaving the hospital, but not before I had strongly warned him with reference to impending stricture, and enjoined on him the absolute necessity of coming occasionally to have an instrument introduced. He left on the 20th June, much fatter than before he entered; the colour of his face improved, and its anxious expression gone. The small glands in the groin had nearly disappeared, and he said he never felt in better health.

About three weeks after, while I was attending a branch dispensary near his residence, he called on me to tell me that his health was first-rate, as well as to exhibit the unimpaired power of the bladder. We adjourned to the cart-house, when he made water six and a half feet straight across the room, hitting the opposite wall with much force two feet nine inches from the ground. While expressing my surprise at the power of his bladder, I could not help remarking that the volume of the stream was not as large as it might be; so I advised him to have an instrument passed through the orifice, but he objected, saying that he was quite well.

In another fortnight he visited me at the same place, with all the symptoms of stricture. On examination, I found the urethral orifice so much contracted that it was difficult to see it at all. I urged him to enter hospital at once, and he was admitted on the 28th July. I began with the smallest bougies, and reached No. 5, the largest that could be passed during his short stay; for on getting relief he insisted on leaving, which he did the 5th August. I should say that the instrument was always tightly grasped by the stricture when entering or leaving it. When he left hospital the stream of water was much larger than on admission, though still diminished in size. The expelling power of the bladder was as strong as ever, as was verified by two medical witnesses, very much to their surprise. I saw him leave the hospital with regret, but he was obstinate and would go.

I did not see him again until the 25th September, when he again visited me. He had great difficulty in making water, and was called up six or seven times at night, and, as he said himself, he "did not warm in his bed." I found the stricture had made great way, the orifice having contracted so much as to be invisible. I had to get him to force and make water before I could see it. The urine came away in the most minute spray, some of it reaching a distance of two feet, while the remainder trickled down the scrotum, which was scalded and irritated. The only instrument I could introduce was a fine stylet, followed, but with much difficulty, by the smallest catgut bougie. By solemnly explaining to him his danger I succeeded in frightening him so much that he became a regular attendant as out-patient, whereupon a decided improvement was made upon the stricture. The irritability of the bladder disappeared, as did the soreness of the scrotum, in addition to which he regained the usual expelling power of his bladder, viz., ten feet—a distance which he effected in my presence and in that of my son, Mr. Agmon B. Vesey, a student of medicine.

March 5, 1869.—It is now more than nine months since the operation. There is no appearance whatever of disease. The glands in the groin are gone, and the skin about the pubis is quite healthy. He has grown fat, and follows his occupation with energy and success. He attends occasionally to have an instrument passed. The firmly contracted orifice will not admit a larger size than No. 4, and that with difficulty, the smaller ones having to be passed first. The bladder possesses its expulsive power in undiminished force; its irritability has disappeared, as has the systolic bruit of the heart likewise.

I consider that this case has a good many features of practical interest. Nor was it wanting in some attributes of doubt and difficulty. It was enough to make a man dubious of the success of an operation when he considered the extent of the disease, its close proximity to the pubis, its long standing, and the enlargement of the inguinal glands. Nor was the operation itself a very simple one, for had the sudden retraction of the corpora cavernosa beneath the skin and pubis taken place before the arteries were tied, the consequences would have been very embarrassing, to say the least of them. I must also draw the reader's attention to the rapid progress of the stricture and its unyielding character, circumstances which should be always borne in the surgeon's memory, inasmuch as all amputations of the penis are very liable to be followed by a like result. But, above all, I would advert to the extraordinary energy with which the urine was expelled from the bladder—a circumstance which makes this case exceptional in the history of amputation of the penis.

I cannot conclude without saying that, in the performance of the operation, I had the advantage of the suggestions of an eminent surgical friend of mine, to whose kindness I was the more indebted that I had myself little experience in the operation, owing to the rarity of cancer penis in this part of the country—a circumstance wherein it contrasts favourably with cancer of other organs, which is very frequent.

March 12th.—I saw the patient to-day, and he is in the enjoyment of excellent health; not the slightest appearance of a return of the disease. I had him weighed this day, and he is *one stone twelve pounds* heavier than he was a fortnight before the operation; and to show how active he is, on the 5th inst. he followed a pack of harriers on foot a distance of ten to twelve miles. It is now nine and a-half months since the operation.

◆

ON THE TREATMENT AND PREVENTION OF PAUPERISM.

By Henry MacCormac, M.D., Belfast.

Man either has or has not the power to control his material condition. I assume that he has the power to control his condition, both materially and morally, for good. The enormous extant pauperism has been ascribed to undue human increase. In my humble opinion this is a profound mistake. An undue increase of population may be the correlative of pauperism, but it is not necessarily the cause of pauperism. I do not for a moment deny that man ought to be governed, in regard to the propagation of his kind, by the same rules of propriety, economy, and forethought which are to govern his conduct in the other relations of life. The brute yields to the generative impulse when it is experienced. He is troubled by no compunction about the matter. Now, a man ought not to act like a brute. He has reason to guide and control his appetites. Too many, however, forget, and act like brutes instead of as men. It would, in effect, prove very greatly conducive to man's interests were the generative impulses placed absolutely under the sway of right reason, chastity, forecast, and justice. Having made this concession, however, which I do most willingly, I cannot go any farther. To ascribe poverty to abuse of the generative instincts merely is to put a part for the whole. It is in argument like what it would be in driving, to place the cart first. The fact is, that the source of poverty is very complex; the factors concerned are at once material and moral. Pauperism, in truth, is referable not to one, but many factors. We may witness dense populations with comparatively little poverty, and, as is notorious, wide tracts where a sparse population is coincident with extreme wretchedness. Pauperism is a social, a moral disorder, and may be got rid of with as great certainty, the proper procedures being resorted to, as small-pox or syphilis, or, as I allege, consumption. It is the result of human incompetency, of defective social concert. I do not make light of the matter. Poverty is a most serious ill; but if we would undertake the cure, we must circumscribe the cause within exact and rational bounds.

The most important thing in this world is man himself. The objects which we term "nature" are very interesting; but man, a single man, is of greater moment than are any amount of rivers, or mountains, or continents, or oceans. It is the presence of man, indeed, that confers value on nature. Without man nature is of no moment whatever. Man brings into the world with him capacities the most wondrous. His powers of production, a circumstance of great importance in the present inquiry, are very great. The labour of a single man, properly directed and aided by modern mechanical means and appliances, is adequate to the creation of necessaries for many men; but the products of the labouring man's industry now and always is and has been on various grounds consumed by non-producers. Now, I hold it as indisputable truth that every man ought to produce in the ratio of his powers. It is a violation of morality when anyone consumes without making a fair equivalent in the measure of his ability in return. The exactions of individuals and of governments have, and have ever had, much to answer for in respect of the production of artificial and really needless want. A higher intelligence, a loftier morality, a better conducted administration, would go far to remedy this great and continually pressing evil.

Social incompetence I esteem as much a disease as is small-pox, or fever, or cholera, or plague, and just as surely remediable. The infant man comes into the world quite at the mercy of those who surround him. By the education and training which are given him he may be rendered a fool or a wise man, an efficient and energetic producer or a little helpless imbecile. Education is not compulsory, and, considering the vast amount of evil agencies and the gross neglect that everywhere prevails, I only wonder that the pauperism and incompetence which now oppress us are not yet greater than what they are. Man, to be sure, has to a certain extent the capacity of forming his own character; but he must be prepared for the exercise of this great power by training. Self-mastery must be preceded by other mastery, the mastery of good and wise and intelligent teachers, as addressed to every single soul. Do I mean to say, it may be inquired, that education and training will prove a cure for pauperism and incompetence, that it will remedy these evils utterly? I do, indeed, mean so to say. I say and aver it, with my whole heart and soul. They would, in truth, prove a complete and permanent remedy for sloth and intemperance, as well as for the absent and ill-directed effort which so harass and desolate the world. Would the energetic, the intelligent, the moral-minded, and in every way competent multitude, which an efficiently enforced, and universal culture would be sure to evoke, rot and pine away in isolation and wretchedness, like Spitalfields operatives or Dorsetshire clowns? The fields of nature—gifts to man of a wise and beneficent God—are fair and wide, and, when resorted to with prudence, manly effort, and intelligence, are competent to yield a smiling home, for countless generations, to every creature that may find it needful and desirable to turn to them.

But what, it may be justly asked, is to be done with the existing mass of distress, or how is it to be got rid of? There is, indeed, a rational and fitting way of dealing with it, as with every other human evil. It ought to be effectively dealt with at whatever cost. A general rate ought to be levied over the whole country, not breaking the hearts and the backs of the poor, and exempting almost wholly the rich. Property should contribute adequately, and the burden not mainly thrown on those who, by reason of heavy and partial rates, are themselves verging upon pauperism. I would diminish, so far as might be, the outlay severally on the army and navy, and apply the proceeds to the effectual decent support of the helpless destitute, the deportation in our idle ships of war to the Colonies of those suited for Colonial life, the formation, so far as it could be done, of factories for the cheap production of the commoner necessaries, the fitting up of kitchens for the economical preparation of wholesome sustenance, of bakeries for whole-meal bread, and, very especially, universal, ceaseless, and effective culture. For any sake, our fellow men ought not to be suffered to languish and pine in wretchedness. The effort ought to be, not so much to mitigate as to remove and abolish pauperism wholly. Pauperism is not only the parent but the offspring of incapacity. It is a beast, a monster, with which we are to hold no terms any more than we should hold them with a venomous serpent, a ravening wolf, or a raging bull. The evil strength of poverty, like that of other great social evils, lies less in its own resistance than in our remissness. It is a sin, an infamy, and a disgrace, all in one, not in the paupers, however, so much as in ourselves. We ought not to palter with or tolerate it at all. It is a remediable ill, and it is a disgrace to our manhood and our intelligence to put up with it.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. Thornley Stoker, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

ADELAIDE HOSPITAL.

Tertiary Syphilis.

(Under the care of Dr. Barton.)

Jemima C., a married woman, 40 years of age, was admitted into hospital January 4th, 1869. The patient, who is a person of much intelligence, gave the following history of her case, which is worth notice, as exhibiting a most complete train of the symptoms of syphilitic disease in their due succession:—

She was infected by her husband about four and a half years ago, being then six months married, and she states that a cutaneous eruption—which appears to have been of the papular variety—manifested itself about two months afterwards. For this affection she was admitted into Dr. Steevens' Hospital, where she was treated with the iodide of potassium and sarsaparilla. She remained in hospital for some weeks, and two months after leaving it was attacked by iritis, first affecting the left eye, and almost immediately extending to the right. She was again received into Dr. Steevens' Hospital, where she was treated for the iritis, but states that she got no mercury.

The eye affection being cured she was discharged; but after the lapse of about nine months was obliged to enter the Richmond Hospital for the relief of ulcers, probably rupial sores, which formed upon her legs, arms, trunk, and head. She was there salivated, mercury being both given by the mouth and by fumigation. She left the hospital cured, in about three months, and remained in tolerable health for a year, after the lapse of which period she began to suffer from severe pains in the head, accompanied by giddiness, dimness of vision, and loss of sleep. These symptoms becoming urgent, she was again admitted to the Richmond Hospital, where she remained about two months, her head being shaved and blistered. During her stay in hospital she suffered from the presence of anthrax on her back, but was discharged relieved of both these, and her head symptoms.

About last May nodes made their appearance, first on her left tibia, and then upon her right; for these she was treated as an extern patient, with the iodide of potassium. Her right knee becoming enlarged and painful, she was, last November, again received into Dr. Steevens' Hospital, and remained there for about two months, being put upon the iodide of potassium and bark, and having the affected knee painted with tincture of iodine.

She remained in tolerable health until admitted to the Adelaide Hospital, last January, when she manifested the following symptoms, which seemed to point to the existence of intra-cranial disease, probably nodes, pressing upon the brain. She suffered from loss of memory, giddiness, and agonizing pain in the head, the pain having the character of a string tied tightly round her head, commencing in the supra-orbital region, and extending hence. Her sight was considerably impaired, light was so painful as to necessitate her being shaded from it, and she suffered from scintillæ or sparks passing across her vision. Her sense of hearing was less acute than natural, and she had a partial loss of taste. Her bowels were torpid and irregular, she could with much difficulty pass water, and seemed in a very debilitated condition.

It is worthy of remark that previous to the commencement of the more acute head symptoms, she was the victim of optical delusions of a great diversity of forms.

Dr. Barton ordered her the biniodide of mercury in doses of one-twelfth of a grain combined with five grains of iodide of potassium in infusion of cinchona bark three times daily. Blisters were at the same time placed behind her ears, she was allowed neither meat nor any stimulants. In twenty-four hours the headache became more tolerable, and gradually all the symptoms showed an improvement. The back of her neck was subsequently blistered with a still further relief, the biniodide of mercury mixture being still used. Dr. Barton persevered in its use until the pain had quite disappeared, and the dimness of vision subsided, while the mental faculties and senses of taste and hearing were also restored. Upon one or two occasions, while under treatment, she took meat for a day or two at her dinner; this invariably produced a return of pain to the head and confusion of thought. She left the hospital at the end of February free from all bad symptoms.

Transactions of Societies.

CLINICAL SOCIETY.

Friday, March 12.

Mr. Paget, F.R.S., President, in the Chair.

The Committee appointed to examine and consider Dr. Day's

CASE OF ENLARGEMENT OF ONE OF THE LOWER LIMBS OF A CHILD,

presented their report, in which they gave the comparative measurement of both limbs and their general appearance. They were of opinion it was an overgrowth of the whole of the right side, and that the subcutaneous lymphatics were distended.

Dr. W. H. Day, at the invitation of the President, gave a detailed account of the case. The enlargement was first detected when the child was two and a half years old. It was at first disregarded, and had gone on increasing ever since. Some medical men thought the enlargement was unreal—that is, that it was confined to the soft parts. In April, 1866, the thigh had grown larger, and the child complained of its aching pain when he ran about. When he was called in it had assumed large dimensions. It was shown to Mr. Paget at that time, and he remarked that he had not seen anything like it in a child so young. In July, 1867, the limb became much enlarged, and at one period he was kept to bed for four days, in consequence of a fluid coming away from the patient; and this year another similar discharge had taken place. Dr. Lionel Beale gave it as his opinion that the fluid was chyle. When the fluid exuded the boy became very ill, and when it subsided he got well again. When Dr. Saunders and Dr. Callender called, the boy had lost much fluid on that and the preceding day.

Several other members related their experience of this and similar cases, and gave their opinion as to the nature of the disease and the fluid which proceeded from the patient.

Mr. Barwell related

A CASE OF PYÆMIA ENDING FATALLY BY COMA.

It was a case which was first in the hands of Sir Thomas Watson and afterwards passed over to him. The patient was a young man of regular life, but had injured himself by violent gymnastic exercises. A maxillary abscess appeared on the right side, the temporal ridge was very strongly marked, the white of the eye was unnatural, the tongue furred, the pulse about 98, the urine . . . .—it was difficult to stop the flow. The young man's temper became so changed that he became insupportable to his friends and medical attendant. He fell into a comatose condition and died, fifty-five days after he came under Mr. Barwell's care. He mentioned another case of a young fellow of rather irregular life. In five days the patient became sullen and discontented, gradually he fell into coma and sank. He believed this change of disposition was one of the earliest signs of the commencement of that fatal malady—pyæmia.

Dr. Julius Pollock mentioned a distressing

CASE OF TYPHOID FEVER

which came under his treatment in December of last year. The patient was twenty-four years of age and, from certain symptoms, severe headache, &c., he at first put it down as an ailment of a neuralgic character, but, after a certain time, symptoms of typhoid fever disclosed themselves. The case growing a serious one he invited Dr. Tweedie to accompany him, and they saw the case together on the 23rd of December. Dr. Tweedie agreed with him that it was a case of typhoid fever, and that the diarrhœa should be stopped by means of opium, which was what he had previously prescribed. The friends of the patient becoming anxious, asked if we had any objection to their calling in Sir Wm. Jenner. They were very glad to have Sir William's opinion, and when he came he agreed with them that the case was a severe one, and that the diarrhœa should be stopped. Two or three days after he found her very weak and perspiring freely; but she fell into a state of coma, and her breathing became so feeble that little hope remained. He had recourse to blistering, and his patient revived so wonderfully that he almost thought she would permanently recover. Sir Wm. Jenner also expressed himself very much surprised at the change that had taken place. But a deep sleep again supervened. He tried blistering again, but with less benefit each time, and the patient gradually sank. He might mention that large quantities of brandy had to be given to stimulate the patient. There was no other special treatment in the case. No *post-mortem* examination was permitted unfortunately.

The President said he could hardly invite any expressions of opinion on the case under such circumstances.

FATTY-STOOLS TREATED WITH PANCREATINE.

Dr. Langdon Down mentioned a case of a man, æt. fifty-two who had been passing a large quantity of fat by the bowels. The man came under his care on the 22nd of September in last year. He learned that he was a native of Boston, and had been suffering in this way for two and a half years. He attributed the affection to having caught a cold while residing in the Fen districts. Ever since then he had been passing fat-like matter of the consistency of bees'-wax. Many years ago he fell from a ship's mast, but got quite well again. He was now carrying on the business of a greengrocer: but latterly he had been so ill that he intended to give up his business. He had lost two stones in weight. The fatty-looking material passing from him had a strong fæcal odour. It was soluble in ether, and was saponified by caustic potash. Careful examination both chemical and microscopical, proved the existence of fatty acids. The urine had a high specific gravity, and contained numerous crystals of oxalate of lime and uric acid. It moreover contained a small quantity of sugar, and he passed four to five pints daily. A year since he had been a patient for five weeks in St. Bartholomew's Hospital under the care of Dr. Farre. His parents had both lived to an old age. Careful examination was made of the abdomen but no evidence of tumour or enlargement of the pancreas could be found. The man complained of present weakness, of pain in the back, flatulence, and altogether was so demoralised, that he quite despaired of getting well again. At first quinine was given, but without any diminution of the fatty stools. On the 1st of October Dr. Down prescribed for him seven and a half grains of pancreatic extract with the same quantity of malt dust three times a day. The improvement was immediate. The number of stools fell to two per diem, and gradually lost their fatty character, while the sugar disappeared from the urine. At the end of November he had only one stool a day, of normal consistence and character. The man so gained in strength and spirits that he was with difficulty induced to remain in the hospital. He at length returned to Lincolnshire, taking with him a month's supply of pancreatic extract. At the end of the month he reported himself in perfect health, and that he had reached his maximum weight. He then left off the treatment, and Dr. Down had just heard from him that his health continued good. During the period of treatment he had been placed on plain diet, and all stimulants had been disallowed. The weight gained by the patient had averaged two pounds per week; one week he gained as much as five and a half pounds. There were several points of interest to which Dr. Down wished to call attention. The case seemed to be just one to test the value of pancreatic extract in emulsifying fatty matters in the intestinal canal, and the truth of Corvisart's statement, that the pancreatic juice would be rendered inoperative by the gastric juice in the stomach. The case was also of interest in reference to diabetes. The co-existence of fatty stools with diabetes had been noticed by several observers. What the real nature of his disease was, it was difficult to determine. In all probability the pancreas was the organ at fault. The man was for a long time seriously ill and had been under varied skilled treatment, and Dr. Down therefore felt that the immediate and continuous improvement under the exhibition of the pancreatic juice must be regarded as other than mere coincidence.

In answer to various questions, Dr. Down said he felt a difficulty in accounting for the persistent good health after the discontinuance of the remedy. It was continued to the end of December. He had heard from the man about ten days since, when he stated that he was in good health and of normal weight. He certainly was surprised to find him still going on assimilating fatty matters after the pancreatine had been discontinued. He took care that the patient should not have a diet excluding fat. The pancreatic extract was always given half an hour after the meal, three times a day. The complexion of the patient was of a tawny hue, and therefore he had examined him with the expectation of finding a tumour. He had a woman under his observation who had a distinct tumour; she was being treated in the same way, with similar results, but he thought it probable that she would relapse if the pancreatine were suspended. In the case which he had brought before the Society there had been a complete discontinuance of the treatment for at least two months, while the man had continued in perfect health.

The PRESIDENT, after thanking the various gentlemen for their contributions, announced that the Society would adjourn to the 9th of April.

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

MARCH 3.

PRESIDENT'S ADDRESS.

GENTLEMEN,—The Army Medico-Chirurgical Society of Portsmouth enters the second year of its existence, and thus far, I venture to say, has, with the kind co-operation of my brother medical officers here and elsewhere, been a success.

On this, the occasion of our first anniversary meeting, it seems to me desirable that we should briefly recur to the circumstances under which our Society was organised, and recount some, at least of our operations. Some of you may remember that the absence was sorely felt of an apartment in which all might meet on equal footing, not only to discuss professional subjects of importance, but to enjoy that social intercourse which, in its absence, was so difficult to obtain. You will also remember that from circumstances which affect us all equally, it was considered desirable to obtain more ready access to the current literature of the profession and allied sciences than, in the absence of our present organisation, was possible,—that therefore much mutual benefit to ourselves, and, through us, advantage to the service, was anticipated from the establishment of this Society. Such were the general sentiments of the medical officers of Portsmouth Garrison early in the year now past; they laboured zealously and well to attain their end, and on the 11th of March last our first formal meeting was held under the patronage of the general officer commanding the district.

Since then we have been honoured with the notice and approbation of the higher authorities, medical and military. Our Director-General has been pleased to honour our Society with his approval; he has sanctioned a very valuable contribution of books being made to us from Netley; he has himself been pleased to present us with some volumes, and has honoured us by becoming patron of our Society; we have been honoured as a society with the approval of His Royal Highness the Commander-in-Chief, and by the Right Honourable the Secretary of State for War. The War Department has been pleased to direct that the apartment in which we are assembled shall be appropriated to our use, and has directed that an estimate for providing it with suitable furniture shall be included in the estimates for the current year.

Nor are these all the flattering recognitions with which we have been favoured. Our brethren in the Royal Navy, and in civil life have been so good as to honour us occasionally with their presence; our brother officers of the military branches of the Army have been pleased similarly to favour us, and I believe that some of our meetings have been attended by gentlemen unconnected either with the medical profession or with the public service.

The public press has likewise been pleased to notice us favourably, and to insert abstracts of our proceedings; the *Hampshire Telegraph*, *Medical Times and Gazette*, MEDICAL PRESS AND CIRCULAR, *Naval and Military Gazette*, and *Broad Arrow*, being the journals to which, on these accounts, we are in an especial manner indebted. The Director-General has also sanctioned the publication of our proceedings in the Departmental Blue Book.

Short as the existence of our Society has been, we already enjoy a degree of access to scientific literature that I believe no other provincial garrison of equal size can boast of. Our subscriptions, small in amount although they be, enable us, thanks to the excellent management of our Honorary Secretary, to receive four weekly, one monthly, and two quarterly, journals, and to obtain from a scientific library in town seven volumes at a time of such works as individual members of our Society may desire to consult. Our funds are moreover in a favourable condition, so much so, that I hope soon to extend still further the advantages we now enjoy.

For this great success of our Society I am deeply indebted to my brother medical officers for their kind and hearty exertions. Had it not been for their co-operation it would have been impossible. I believe I may instance our success as one of the many good results that arise from mutual understanding and good feeling among officers labouring together, and would express my trust and hope that similar sentiments may exist between us in the further duties that are still before us.

I would desire to record my acknowledgment, and that of our Society, to Surgeon-Major Fleming for the valuable and extensive selection of books and plates with which he has favoured us; to Assistant-Surgeon Maunsell, R.A., for his collection of fossils, now on the side table; to Assistant-Surgeon Tate, and to Mr. Tyler, for the beautiful collections of shells for which we are indebted to them; and to the various other gentlemen who, by donations of books, periodicals, and in other ways, have specially assisted us.

The list of papers that I am about to read, as having, during the past year, been laid before our Society, will, better than any remarks of mine, indicate the variety and extent of our labours; thus, to Surgeon POULTON, 35th Regiment, we have been indebted for an interesting account of a case of aortic aneurism bursting into the pericardium, and for some clinical remarks on a case of sporadic cholera that occurred in a soldier of that corps.

Assistant-Surgeon BALL, 33rd Regiment, read a full and interesting report on the Medical Transactions during its service in Abyssinia; a report so interesting as to have subsequently been appropriated by several of the newspapers.

Assistant-Surgeon PARK, R.A., described the manner of employing carbolic acid in the treatment of extensive wounds, illustrating his remarks by the case of a soldier under his care, who, under its use, made a very rapid and complete recovery from a compound comminuted fracture.

Surgeon FRANKLYN, R.A., read an important paper on the subject of recruits and recruiting, and on a subsequent occasion exhibited to the Society in the microscope preparations of guinea worm, describing at the same time the case of a soldier who is believed to have contracted the parasite in Abyssinia.

Surgeon LAMPREY, 67th Regiment, has favoured us with remarks on the treatment of bubo by carbolic acid; on the treatment of indurated chancres with the same remedy; on two cases of aortic aneurism treated by him; and on a new description of suture used by himself.

Staff-Surgeon ROCH has given us the benefit of remarks on the "Golden Fleece," lately a hospital ship employed in the Red Sea; on heat apoplexy; and on the natural history of the Red Sea and coast of Abyssinia.

Assistant-Surgeon MAUNSELL, R.A., has communicated to us a paper on aortic aneurism, exhibiting at the same time morbid preparations, and a cast illustrative of that disease; one on the statistics of the malady; clinical remarks on a case of depression of the internal table of the skull caused by a homicidal wound; one on mortality in India as influenced by temperament; and some valuable notes in illustration of the geological specimens already alluded to.

Assistant-Surgeon TATE has communicated a valuable list, accompanied by remarks on the land and fresh water shells of Hampshire.

Assistant-Surgeon ALCOCK, 35th Regiment, has contributed a report of a case of ulcerated larynx speedily terminating in death; a case of aneurism; and a very scientific paper on the power exerted by nervous influence on temperature.

Surgeon PORTER, 97th Regiment, has communicated a case of abdominal aneurism, and one of vesical calculus, the stone of large size, and very successfully extracted.

Assistant-Surgeon CLARKE, R.A., has given us a carefully prepared paper on malingering; Assistant-Surgeon **Bruenn**, 67th Regiment, a case of aortic aneurism; and Surgeon **Perry**, R.A., two very suggestive cases of pleuro-pneumonia; Assistant-Surgeon **Bredin**, 97th Regiment, a paper on the influence of the nervous type of disease on military service of soldiers, as well as with remarks, and a preparation illustrative of aneurism of the aorta.

Assistant-Surgeon **McFall**, 34th Regiment, was so good as to send to us his report of a case of suicidal wound in the head, and to present us with specimens illustrating the injuries occasioned by the bullet in its progress.

A paper of great importance, on yellow fever, by Inspector-General **Lawson**, was by him placed at the disposal of our Society, and in the discussion which followed the reading of it, Sir David Deas, K.C.B., was so good as to favour us with the results of his extensive experience in the treatment of that disease.

Staff-Surgeon **Cullen** communicated an able report on cases of cerebro-spinal meningitis that occurred in the 11th Dépôt Battalion; Surgeon-Major **Manifold**, 34th Regiment, supplemented it by remarks on cases of the same disease that had come under his observation, and Dr. **Coleman**, R.N., read a paper descriptive of it that had been prepared by Dr. McDonald, F.R.S., of that service.

Dr. **Jesset**, a civil practitioner, favoured us with a paper descriptive of his experience in the use of carbolic acid as an external application; and Dr. **Elliott**, R.N., at a late meeting, gave an important paper, in which were ably set forth his reasons for believing in the communicability of phthisis.

ANTHROPOLOGICAL SOCIETY OF LONDON.

March 16th.

Dr. R. S. Charnock, V.P., in the Chair.

Mr. L. Owen Pike read a paper

ON THE ALLEGED INFLUENCE OF RACE UPON RELIGION.

The author commenced, that in his opinion revelation was not within the province of scientific investigation, and that it was no part of the duty of a scientific society to question the truth of one form of faith, or maintain the truth of another. But, though anthropology could not deal with revelation, it could deal with the persons accepting it; it could compare mind with mind, race with race in all the differences and all the resemblances, which they exhibit in their faiths. And this, he trusted, could be done, not only without exciting animosity, but with the approbation of every sect. Mr. Pike maintained that difference of race was not the chief, nor even an important cause of difference in religion, and that any race might to all appearance, hold any creed. His first illustrations were drawn from the various forms of Christianity, The Germans are principally Roman Catholic in the south, but Protestantism and Romanism flourish side by side in the north; the Southern Hollanders and the Northern Belgians, though of common race and language, are at the opposite poles of Christianity and equally earnest in their respective creeds. France and the border land connecting the three falsely called Latin nations, though now remarkable for their orthodoxy, were, in the twelfth century, the very hot-bed of heresy. So, too, when Augustine came to England, the Christians of Ireland agreed with those of Wales and Scotland in opposition to the Church of Rome; and, after a great variety of changes, Wales has become the stronghold of Calvinist Dissent, while Ireland is the stonghold of Romanism. The author then pointed out that Buddha, whose first converts were natives of India, has had the most important influence upon the inhabitants of China, who are of wholly different race; that the faith of Mohammed has been accepted, not by Arabs, but by Turks, and even by Hindoos; that in ancient times the gods of the conquered provinces found, not only altars and temples, but worshippers at Rome; and that in our own times we succeed in converting savages to Christianity.

An attempt was then made to account for this strange and, at first sight, inexplicable distribution of religions. An opinion was expressed that, although the broad general outlines of any creed are commonly accepted by whole nations or numerous sects, the details are filled in according to the disposition of the individual. The imperfection of language as an exponent of thought might explain, in part at least, why different races are apparently of the same religion, and why different sections of the same race are apparently of different religions. The general conclusion was that, although there may probably exist certain race-elements in the religion of every people, they are of minor importance, and cannot be defined in the present condition of language and psychology. Dr. C. Carter Blake, Dr. Beigel, Dr. Nicholas, and other gentlemen took part in the discussion which was adjourned to the 6th of April.

SURGICAL SOCIETY OF IRELAND.

The Society held a meeting on Friday evening, March 5th, in the Albert Hall, Royal College of Surgeons,

Mr. Porter, President of the College, in the chair.

Members present:—B. Wills Richardson, Hon. Sec.; Drs. W. Moore, Morrogh, Willis, Roe, Murdock, T. Stoker, Purcell, Jameson, Henry Gray Croly, R. Fennell, Robinson, Stewart, Brassington, Wharton, Henry Kennedy, J. Hawtrey Benson, Charles Benson, Hon. Sec.; Shannon, White, Buchannon, Mapother, O'Grady, Colles, Jacob, Guinness Beatty, R. Daniel, Hewitt, Churchill, jun., Brady, C. Fleming, Stapleton, Stokes, jun., and Henry Croly.

PRIMARY CANCER OF THE LIVER.

Dr. John H. Benson said:—

These specimens, Mr. President, were taken from the body of a man, æt. seventy-one, who died under my care, in the City of Dublin Hospital, a few days ago. He stated that he had always been a healthy man up to about a year since, and that then he began to suffer from a sense of uneasiness and weight in the right side, which gradually increased up to the date of his admission, but was at no time severe. He also stated that he had lived temperately for many years. However, I was told that he boasted to the other patients in the ward that he usually drank about nine glasses of whiskey before breakfast.

On admission, the patient complained of a "soreness," to use his own expression, "from the groin to the shoulder," and on examining the right side I found evidence of a very large liver. It extended downwards almost to the umbilicus. There was considerable tenderness over the whole liver, but it was especially marked in certain spots. On palpation a sense of hardness was communicated to the hand, but I found it impossible to say whether the surface of the liver was smooth or otherwise, owing to the tension of the recti muscles whenever pressure was made on the part. Notwithstanding this tenderness, there was a total absence of pyrexia; pulse 65, regular, but small; tongue slightly furred. No œdema existed anywhere, nor any ascites. The urine contained a small quantity of albumen. Judging, then, from the absence of pyrexia, from the apparently slow development of the disease, from the history of his intemperate habits, and from the absence of signs of organic disease in any other organ, I was induced to set the case down as one of either ordinary fatty, or of amyloid, disease of the liver, and I treated it accordingly.

For nine days the patient progressed favourably, saying that he felt better from day to day. On last Monday, however, the fifth day from admission, he did not feel so well, and for the first time a slight jaundiced hue was perceptible over the body. On next day the yellow colour of the surface was intensified; the urine was tinged with bile; pulse 104, small and irregular; respiration 25, deep and thoracic. He lay in a kind of torpor, but when spoken to, he roused up and answered intelligently. This semi-comatose condition directed my attention to the kidneys, but I found that the urine was copious in quantity. On Wednesday all the symptoms were seen to have become considerably aggravated, and in the evening he sank and died.

On opening the abdomen, assisted by my colleague, Dr. Hewitt, we found from about four to six ounces of fluid, containing a large proportion of blood, in the cavity of the peritoneum. There was no evidence of peritonitis. Numerous petechial extravasations of blood, varying from one to three or four lines in diameter, were visible in the mesentery. The liver was found enlarged, to twice its normal size, weighing 8 lbs. 5¼ oz. The substance of the liver in parts presented somewhat the appearance of the amyloid disease; but, on applying the iodine and sulphuric acid test, no characteristic reaction took place. The greater portion of the liver, however, was of a purplish red hue. Besides this alteration, we discovered numerous tumours, varying from the size of a hazel-nut to that of a small orange. They were invariably raised above the surrounding surface, and with a very few exceptions were of a much darker colour, and somewhat softer and more elastic to the touch than the surrounding structure. They were not depressed in the centre. When cut into, they presented a circular or oval section, with a well-defined margin, and their substance projected with a slight convexity, about equal in degree to that of a watch-glass. With few exceptions the diameters of the tumours when cut into were found to be considerably greater than that of their disc which appeared on the peritoneal surface of the liver. Dr. John Barker kindly examined one of these tumours, and pronounced it to be medullary cancer. On raising the liver, we found that the lymphatic glands in the transverse fissure were greatly enlarged, and were so soft that a slight pressure of the fingers reduced them to a soft grumous pap.

Suspecting these tumours to be cancerous at the time we discovered them, we next proceeded to look for cancer elsewhere. The stomach contained some dark, altered blood, but no cancer existed these. The intestines and the other abdominal organs were equally free. On opening the thorax, we discovered a number of enlarged glands on the right side exclusively of the anterior mediastinum.

In the apex of each lung we found a few old tubercular masses, which had undergone calcareous degeneration, and a very few small old cavities, but no trace of cancer was perceptible. However, while opening the pericardium, we discovered a tumour, about the size of a walnut, situated in the angle formed by the junction of the pericardium and diaphragm. This tumour I examined myself, and found it to be cancerous. A few enlarged glands were found in the right side of the neck. No other traces of cancer, beside those I have mentioned, were visible anywhere in the body.

The heart had undergone some fatty degeneration. A few calcifications were imbedded in the substance of some of the chordæ tendinæ of the left side, and in the left zona tendinosa. On the free edge of two of the tricuspid flaps we found a somewhat bulbous smooth swelling, yet these gave rise to no murmur during life.

The kidneys presented appearances due to Bright's disease, and in some places may be seen that appearance of the pyramids said to resemble a sheaf of wheat. On one of the kidneys we saw a large cyst, such as we sometimes find in cases of Bright's disease.

This case, Sir, is interesting, I think, as presenting an example of primary cancer of the liver, which we know to be rare, and as not exhibiting many of the most important diagnostic symptoms of that disease. The entire absence of cachexia, or of pyrexia, and the apparently slow progress of the disease, the suddenness of his death, and the absence of cancerous disease in other organs, are remarkable; while the only diagnostic symptom of cancer present was the slight pain and tenderness, which might naturally be supposed to have arisen from other causes. The age of the patient, too, was somewhat unusual. Out of eighty-three cases analysed by Frerichs, with reference to age, only two exceeded seventy. This patient's age was seventy-one.

(*To be continued.*)

DUBLIN PATHOLOGICAL SOCIETY.

February 20.

ON CONSTRICTION OF THE MITRAL ORIFICE.

Dr. **Hayden** submitted to the Society two hearts illustrating the subject of constriction of mitral orifice, which in Dublin, at least, was a comparatively new subject, and one upon which there was still a great difference of opinion. These specimens were somewhat old, but he thought the subject was new and interesting. The first of these hearts was taken from a boy ten years of age, who was admitted into hospital under his care on the 3rd February, 1868. He learned that five years previously the boy had scarlatina and spat blood. When he saw him the first time the pulse was not recognisable; he had quick respiration, cough, and mucous expectoration; he spat blood once every three weeks; the hæmoptysis continuing three days, and always bringing considerable relief to his symptoms. He remained under treatment a short time and left hospital at his own request much relieved, but without any alteration in the physical signs. The prominent physical sign was at the apex of the heart, a loud and rough free systolic murmur; and from this he had no hesitation in diagnosing constriction of the mitral orifice. He presented himself again at the hospital in the end of February, and again on the 23rd March. There was no change, except that on the last occasion he (Dr. Hayden) discovered at the apex of the heart both a systolic and a præ-systolic murmur. He continued to spit blood in large quantities, and was readmitted on the 22nd June. He was then universally œdematous, with effusion into the great serous cavities, face pallid, lips livid, and no pulse at the wrist; the pri-systolic murmur less pronounced, but yet distinct. He died in a few days; and on a *post-mortem* examination the following was the condition of the heart:—There was a very little alteration found in the right cavities, the right ventricle was a little dilated, the auriculo-ventricular orifice considerably dilated, three fingers passing through it easily, the left auricle was considerably dilated and thickened, the mitral orifice was much reduced in size, so much so that it barely admitted the barrel of a quill, the left ventricle was in a normal state, neither dilated nor thickened, the pericardium was found firmly adherent to the heart. The second case was that of a female, aged thirty, who came up from the west of Ireland to be treated for jaundice. She complained of no other illness whatever. The jaundice appeared for the first time four months previously, and one month after her first confinement. There was no complaint of pain or any symptom to attract special attention to the chest. The pulse was 84, the colour of the skin deep yellow, she passed urine in large quantities. There was scarcely any tenderness in the hypochondrium, and in a hurried examination of the heart made over the patient's dress he thought he detected a faint systolic murmur. The symptoms, however, were not of a kind to attract any further attention to the heart until the 1st of July. She had then undergone considerable improvement; the jaundice was less decided, and she was making arrangements to return home. She told him (Dr. Hayden) on that day that she had a fluttering about the heart, and he made a careful examination of the organ in the corridor of the hospital where she was walking at the time, and declared at once that it was a case of constriction of the mitral orifice in the absence of any other evidence of heart disease. On the 3rd of August she was struck down with typhus fever. He saw her on that morning, and the pulse was then 120; the murmur at the apex of the heart was still more decided in character. On that day he left home for Oxford, and when he returned he found her body covered with dark spots interspersed with petechia. She died on the following day. There was about a pint of fluid found in the pericardium; the heart weighed 11½ ounces; the right cavities of the heart were in the condition already mentioned when speaking of the first organ; the right auriculo-ventricular orifice was dilated as in that case, but the right ventricle had undergone no change, either as to the thickness of its walls or the size of its cavity; the left auricle, as was invariably the case, was enlarged and thickened; the mitral orifice was constricted; it presented the character known as the "button-hole constriction;" the valves were agglutinated at the margin, leaving a button-hole slit through which the point of the index finger alone could be made to pass; the cordæ tendinea were shortened and thickened; the left ventricle had undergone no change, being of the ordinary size and thickness. He should not further dwell on this subject, except to say that the two cases submitted to the Society afforded a forcible illustration, not only of the practicability of diagnosing constriction of the mitral orifice, but likewise of its comparative facility. In the latter of the two cases there was no evidence whatever of disease of the heart, with the single exception of the characteristic præ-systolic murmur at the apex; yet from this single sign he had no hesitation in making the diagnosis of mitral constriction. One or two features were worthy of notice: first, the suppression of the pulse in the most of these cases, and the remarkable apathy in regard to their state, and absence of suffering, the patients walking about the ward with no pulse perceptible, and declaring, if questioned in regard to their health, that they were better; and lastly, the frequent recurrence of hæmoptysis, which was a symptom to be met with in every one of these cases.

DIFFERENT FORMS OF CROUP.

In a lengthy paper on the pathology and treatment of the Different Forms of Croup, in the *American Journal of Obstetrics*, Dr. A. Jacobi gives the results in 203 cases of tracheotomy for croup, occurring in New York in the practice of himself and three other physicians. Of the entire number, 50, or nearly twenty-five per cent., recovered.

IN APRIL.

The First of a Series of Six Lectures

ON THE

PATHOLOGY AND TREATMENT OF FIBROUS TUMOURS OF THE UTERUS

(INCLUDING POLYPI),

WILL APPEAR IN OUR SECOND NUMBER IN APRIL

BY JAMES PALFREY, M.D., M.R.C.P. LOND.,

Assistant Physician-Accoucheur to the London Hospital;
Late Physician-Accoucheur to the Farringdon Lying-in Charity, &c., &c.

CHAIRS OF PUBLIC HEALTH.

AMIDST all the lecturing to which students are subjected it is somewhat strange that the subject of Hygiene has not yet been able to attain the dignity which is its due. It is well known that we are by no means advocates of a system of over-lecturing. We have, on more than one occasion, urged that certain subjects should be relegated to the students' preliminary education, and so eliminated from his professional curriculum. Is it not manifest, for example, that Hygiene is far more entitled than Botany to a professoriat in a medical college? Yet Botany has always been compulsory, while Public Health has been ignored. We are not here concerned with the question of compulsory attendance. We do not just now propose to argue whether Botany or any other science should occupy its present place in the curriculum. We are rather wishful to avoid all comparisons, and merely to draw attention to the glaring anomaly that, while all our medical schools profess to afford complete instruction in all branches of a medical education, they have hitherto made no provision for such a subject as the Public Health. We are perfectly aware that this and every branch of State Medicine has been, by many lecturers and others, regarded as comprised in the compulsory attendance on Forensic Medicine. These gentlemen have, therefore, conscientiously devoted from two to six lectures to what they variously call State Medicine, Public Health, or Hygiene. For this they certainly deserve all credit, especially in the smaller schools, where the temptation to negligence on the part of the lecturer is too strongly seconded by the smallness of his class.

Should those who have adopted this plan be encouraged to enlarge it in accordance with the growth of their subject? Should, rather, an additional course of lectures be inaugurated? To these questions directly opposite answers will be given by those who have studied the subject. Those who feel how much the student is burdened by the weight of many lectures will resent the proposal to add another course. Those who desire to see our schools complete will admit the urgency of some decisive steps.

The creation of a Chair of Public Health by University College will bring this question to an early issue, and the committees of the various schools will probably be shortly discussing the propriety of following the example, or of postponing a decision. It is, therefore, a very appropriate time to direct attention to the question. First of all, it should be borne in mind that University College is more than a medical school. It instructs equally in the other faculties, and requires, therefore, a much more complete staff. Completeness is, therefore, to that College an ideal which others do not aspire to. University College, therefore, whatever the changes in her strictly medical compeers, might well retain chairs they could abandon, and, by parity of reasoning, institute others they might omit to add to theirs. Botany, Zoology, and other subjects would naturally be professed at such a college, even though medical colleges omitted them, and examining boards ignored them; further, even though few other than medical students attended them. University College teaches preliminary as well as professional subjects—completely educates for every profession. It may, therefore, as naturally afford a chair for any new subject as it may for classics, mathematics, modern languages, &c. *Per se*, the fact that University College teaches Hygiene is, then, no more an argument for medical colleges erecting such a professorship than that, by force of example, they should teach Latin, especially while this latter is demanded by the examining boards.

There are, of course, many who would like to see Latin and all other needful subjects systematically taught at each of our medical schools, and the appointment of a few tutors in addition to the professors in our schools might really be advantageous to a certain proportion of students. But so long as medical schools remain what they are, there are only a few who would advocate the change. The many feel for the student; they see the lecture system has been too fully relied upon, and dread any addition lest it should be advanced to the compulsory list. In this state of public feeling the advocates of the *status quo* will probably be able to defeat any attempt to multiply the courses, at any rate for the present. Still, the subject of public health is one of great and growing importance, and its devotees will not fail to urge the importance of its recognition. We feel as forcibly as any one that hygiene is properly a part of the instruction of all medical men; and the knowledge of those outside the pale of the profession is so rapidly enlarging on all such questions, that ignorance of them will be sure to lead to loss of confidence on the part of patients. Students may therefore be urged not to neglect the subject of public health, after the manner of those who only desire to get through College and Hall, without caring for the responsibility of practitioners.

On the other hand professors of forensic medicine, to whose subject in reality appertain all the branches of state medicine, may be reminded that hygiene is continually growing in importance, and therefore demands increasing attention. Whether they choose to give state medicine greater prominence in their course, or whether they think well to give a few supplementary lectures—optional for the student—on public health, is of little moment. Either plan would really suffice for all that is at present necessary, and in the transition stage of the curriculum, as it now exists, would easily adapt itself to future exigencies. We are inclined to think that the lecturer on forensic medicine at each school might advantageously give some extra attention to the needs of students in the present day, by making hygiene a more prominent feature in his course; and with a view to this, where extra supplementary lectures are not given, it might be as well to add the words "and public health," after lectures on forensic medicine, in the prospectus of the school.

It will be seen that we fully recognise all that these lecturers have already done, and we can bear personal testimony to the efficiency with which hygiene has been taught by some lecturers on forensic medicine. We could name one or two gentlemen whose courses last year were particularly complete in this respect. We refrain from doing so as we are sure the invidious distinction would prove unwelcome to them, and besides, it is possible that others may have done just as much, although their work did not happen to fall within our personal knowledge. We may say this, however, for the encouragement of any one who needs it, that the subjects under discussion appeared, as far as we can judge, quite as attractive to the majority of students, as any of those usually included under the term forensic medicine. The summer session will soon be upon us. Lecturers have therefore time to make up their minds on the point.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Another meeting of the *Comitia Majora* will soon be convened, and we need scarcely add with what anxiety the issue will be awaited by all who desire to see a decided check given to a long career of illiberality on the part of some of the College authorities. Our readers are, doubtless, aware of the manner in which one proposed measure of reform, viz., the mode of election to the Fellowship, has, by a cunning device, been frustrated and, as matters stand at present, reduced to a *minimum* of value.

Such a result, however, might, from bygone experience, have been expected to follow any attempt to induce the College authorities either to modify certain of their bylaws, or even to carry them out in the spirit in which they were originally framed.

In these liberal times it is sad to find that an Institution which can well afford, indeed has every inducement to be less exclusive, "makes no sign," notwithstanding earnest and repeated remonstrance, but still resists just demands; and still more sad to learn that some of the positions of this stronghold of Injustice have not been more resolutely carried; but—

> "Freedom's battle once begun,
> * * * * *
> Tho' baffled oft, is ever won."

It is pretended that the recent liberal proposal to modify the mode of election to the Fellowship might open a door to certain abuses, such, for example, as canvassing or, to use the more technical phrase, "*solicitation*," but whether such an evil would be carried to a greater length than under the existing mode, would form a curious subject for enquiry; at all events, if discovered, it would meet, from the general body of Fellows, with a deservedly stern rebuke. We can quite believe that there are many members of the College and those among the most deserving of election to the Fellowship, who would feel themselves greatly humiliated by a recourse to such unworthy means.

We have always maintained that the Council of the College should no longer be permitted to claim a vested right as regards the secret nomination of Members for the Fellowship.

It is a power too important to be delegated to a small and irresponsible body of men; one, moreover, liable to abuse and (perhaps not without good reason) always open to the suspicion of abuse. All nominations should be made in the presence of the general body of the Fellows, to whom (unlike most other scientific bodies) the merits of the respective nominees would be pretty generally known.

We would fain believe that the injudicious attempt to oppose the progress of reform will be defeated at the coming meeting, and that the liberal section of the Fellows, feeling how useless it is to temporize further, will evince a determination to effect the changes so looked for by the Profession, and so necessary to revive the flagging loyalty of the College Members.

Should such a consummation be effected,—disappointment, at times, there might be—but no cry of injustice would henceforth find echo either within or without the time-honoured hall of the Royal College of Physicians of London.

◆

FEES TO MEDICAL MEN.

If medicine is to maintain its position as a profession, and not a trade, it will be essential that the licence which is accorded to medical men to vary the amount of their honorarium according to the position and circumstances of their patient should remain unchallenged. This power is just the line which separates a profession, in which the fee is an arbitrary remuneration, and the trade in which the sale is effected for a fixed sum to all comers. Wherever the etiquette of the *honorarium* has been suffered to be disregarded, the practices of the profession has lapsed into something little better than open trade, and it behoves the profession, therefore, to stand most fixedly to the point, and discountenance effectually any practices which might tend to its abrogation.

The most obvious argument against an arbitrary fee is the possibility of extortion to which the liberty to fix the amount might give rise; but this is not a difficulty which affects every-day medical practice. If a medical man overcharges a patient, there is no hindrance to the patient relieving himself of the extortionate claim by calling in some other adviser, and the doctor therefore takes care to use carefully his powers of fixing his fee, and to keep well within the line where extortion begins. But where the patient has died, and there are only executors to deal with, past services to assess and no future benefits to forfeit, then is the temptation to overcharging greatest, and it behoves the profession to see that such opportunities are not used to its own derogation.

A Dr. Clarke has recently, by such a procedure, brought himself under the eye of the law, and, as we think, sacrificed the character of the profession for fairness for personal objects. He sued the estate of two wards in Chancery for £310 for attendance on them. Twenty-nine visits, at £1 1s. each, for what is described as a "slight" illness; £289 for attendance, at £1 1s. per visit; two visits to Worthing, at £31 10s. each; three visits to Brighton, at £26 5s. each; and £42 for letters and calls on solicitors in the suit. These are the charges demanded by Dr. Clarke as the fair and moderate remuneration of a general practitioner at Pentonville. Even his own counsel did not offer evidence that the amounts were usual or just, and said that he "would not contend that the whole amount of £310 could be recovered. The guardians had tendered £105 in discharge of the bill. At the conclusion of Dr. Clarke's case, his lordship asked if the tender of £105 was repeated, and being told it was, said that he considered it in excess of what Dr. Clark was entitled to; therefore he should dismiss the summons, with costs from the time of the offer having been first made. His lordship said that he should have disallowed the charges for journeys to the country and have reduced the charges for visits to town, and should have disallowed a lump sum of forty guineas charged for visits to solicitors and other persons interested in the suit. If the arguments of the claimant's counsel prevailed, doctors might make what charges they pleased, according to the fortune of a patient, and it would be necessary to make a special bargain with a doctor before employing him."

We believe we are joined by the entire profession in our opinion that such a claim on the part of one of its members is disreputable, and could not be defended even on the wildest estimation of Dr. Clark's services.

◆

THE SUPPLY OF MEDICINES FOR IRISH DISPENSARY DISTRICTS.

The intentions of the government with reference to the allocation of a portion of the revenues of the disendowed church to the maintenance of skilled nurses for the poor are already shown. We are in the position of announcing that Mr. Gladstone feels strongly the absolute necessity of making some such provision for the requirements of Irish Dispensary Districts, and that without regard to the source from which the funds for the purpose may come, it is very probable that an extensive system of local nursing will receive the energetic support of the ministry. We understand that an official representative has been in communication with Dr. Evory Kennedy, of Dublin, on the subject of trained midwives, and requested that gentleman to submit on paper his views on the subject. This communication which we give *in extenso* below, has been submitted to Mr. Gladstone, who expressed his sense of the importance of the subject and of the facts which Dr. Evory Kennedy has made public. The following is the text of the letter :—

Dear Sir,—I have much pleasure in complying with your wish that I should state my impressions on the subject of a proper general supply of well educated nurses (midwives) in the dispensary districts in this country. In expressing my convictions of the necessity of such a supply I must say that in no department of the poor relief dispensation does there exist so urgent a want, in none are the pressing calls of humanity so neglected. Whilst at the same time the facilities for supplying the want and remedying the neglect are at hand, and easily rendered available.

My occupations have for the last 35 years rendered me but too familiar with the details of the miseries caused by neglect, ignorance and mismanagement amongst the females of the lower orders in the country districts in their labour; some of the worst, most hopeless and most deplorable cases under my own care in hospital and in the several hospitals that I visit as a governor, are due to injuries absolutely inflicted by mismanagement, or occuring necessarily from neglect at this time. Cases, most of which might have been prevented by skilful treatment and proper care. Such are lacerations of the bladder and womb—followed by incontinence of urine for life. Occlusions, displacement and deformities of the organs rendering subsequent capital operations necessary.

These are among the least mischievous results of the want I allude to; as immediate fatality both to mother and offspring are of not unfrequent occurrence from the same cause. Indeed, when we contrast the consequences in many of those cases, that survive their labour, it is a question of little doubt that death would have proved a preferable alternative.

Again, it is an opprobrium to the Poor-law arrangements, however perfect those may be, in other respects, that frequent complaints are made of the neglect of the Dispensary physicians, in his midwifery attendances. We too, frequently find such cases, the subject of investigation by the Poor-law Commissioners; and the cause of grave censure upon the medical attendant, when, the fault lies, perhaps, not so much with the physician as with the imperfection of the system—in other words, from expecting the dispensary doctor to do impossibilities.

With the urgent general engagements of the dispensary physician, it is quite impossible that he should remain sitting by a patient in labour for hours, perhaps days, until interference becomes necessary. If he do so, it must be done to the neglect of his many other, perhaps more urgent engagements. In those dispensaries where competent, instructed, nurse tenders are available, the nurse is sent for on the commencement of the labour, remaining with the patient until its natural termination; or, if interference becomes necessary, she summons the physician at the right moment, when the necessary operations are had recourse to, and the mother and child saved, if possible; and thus mutilations and after misery are prevented by proper interference at the right time.

As it is at present, where no educated nurse tender is available, the physician is either summoned too soon—in which case his other engagements preclude his remaining with the patient—or too late to render the resources of his art available; the deplorable consequences above described occur, and the physician is not unfrequently unfairly accused of neglect.

So much for the necessity for skilled nurse tenders. Now for the facilities that exist for obtaining and utilizing them.

The Poor-law guardians certainly at present possess the power of employing them; but when we recollect that they have possessed it for several years, and that out of the eight or nine hundred dispensary districts in Ireland little more than a fourth are provided with them, it is quite clear the plan of leaving it optional with the guardians to employ dispensary skilled nurses will never accomplish the object. It should on the contrary, be rendered imperative to have at least one well instructed nurse attached to each dispensary; and, when the population and wants of the district require it, more than one.

The expense to the rate-payers might be lessened by making the nurse tender also the care-taker and occupant of the dispensary. The allowances and free house given at present to the housekeeper constituting a portion of the skilled nurse's remuneration; the objection of her absence from the dispensary, on sick calls, being met by the nurse tender always undertaking to have a relative or friend living with her who should attend to these in her absence.

In obtaining a sufficient supply of well qualified nurses, great facilities exist in Dublin. In the great Rotunda Lying-in Hospital, and the Coombe Hospital, both institutions assisted in their support by Government grants, and the governors of both of which institutions facilitate in every way the imparting instruction to both male and female pupils, particularly for attendance on the poor. As it is, the former institution educates annually about sixty female pupils; but this number could easily be doubled, or quadrupled, if necessary; the only difficulty being the finding accommodation for their residence—a difficulty, however, not insuperable, as the Board of Public Works were good enough to express their readiness to grant money to erect an additional building to accommodate female pupils attending the Rotunda Lying-in Hospital.

The governors, two years since, directed their attention to the subject of increasing the facilities for educating female pupils when the fee for admission was lowered by the master in order to induce the Poor-law guardians to send up pupils—an advantage which I regret to state they did not avail themselves of to any considerable extent.

I should perhaps mention that by an old Act of Parliament the Grand Juries in this country exercised a power for many years of presenting a sum of £30, to be applied to the education of each female pupil sent for education to the Rotunda Lying-in Hospital, a power exercised on an extensive scale, but which ceased to be acted upon after the introduction of the Poor-law into this kingdom. In order to show the difficulty, not to say impossibility, of carrying out the supply of skilled nurse tenders to dispensaries on the present permissive plan, I may mention that upwards of two years since I succeeded by great exertion, as an *ex-officio* Poor-law guardian of the union in which my country residence is placed, in getting the sanction of the guardians to the appointment of a nurse to the Clondalkin Dispensary district; but as yet the office remains unfilled up. Nothing but a compulsory law securing the appointment of well educated midwives at all dispensaries will meet the case.

Twenty years since, as a member of the Dublin Cow-pock Institution Directory, I assisted in pressing compulsory vaccination upon the Legislature. It was then scouted; but until adopted the efforts to render vaccination general and check small-pox were futile, whilst the results now fully justify the recommendation.

We may trust that similar success shall not only attend your efforts to meet the deplorable neglect of the poor parturient females in their trying hour; but that your attention having been thus called to the subject of nursing, and its important bearing upon the interests of the lower classes, the other branch of the subject, that of procuring a supply of skilled nurses to superintend the treatment of the sick in the poorhouses and in their own dwellings, may also form a part of any general scheme to be carried out in this country. The testimony of all hospital and dispensary physicians upon the amount to which this system abbreviates disease and suffering, or in other words, lessens mortality, is conclusive, and by consequence reduces mortality. It is only a subject of astonishment that those entrusted with charge of the sick poor do not, from the sordid motives of economy alone, adopt the plan of employing more generally skilled nurses; and thus, by slight increased preliminary outlay, effect a large pecuniary saving.

I have the pleasure to be,
Yours, very faithfully,
(Signed.) EVORY KENNEDY.

EDUCATIONAL REFORM.

THE series of articles on educational reform which we have been publishing in our columns will be continued as soon as possible. The writer has still to treat the medical curriculum in a systematic manner. Up to the present time he has been occupied with laying down general principles, combating objections, criticising the views of others, urging the necessity of corporate reform and reform of the Medical Council in order that the required changes may be effected, and pointing out the facility with which, even under the present system of a number of different licensing bodies, certain much needed improvements may be made in the curriculum, or rather the curricula. There remains for the completion of the series the suggestion of such a curriculum as it would seem advisable for a Medical Council with absolute authority to promulgate as necessary to be passed through by candidates for the minimum qualification which almost all medical reformers desire to see established.

This interval in the series is a favourable opportunity for "A Medical Teacher" and others to criticise the views expressed, and we invite a free discussion.

SCOTLAND.

EDINBURGH.

INFIRMARY SITE.

THE old question of the Infirmary site may perhaps by this time have lost some of its interest to our readers. So much has been said on both sides, reiterated time after time in correspondence in the newspapers, and in speeches and reports at meetings, that it seems impossible to expect that one new suggestion should be made; and we come to the conclusion almost that the authorities will have to decide the matter solely on the *data* they already possess. Still, the subject is one of such grave moment, involving consequences bearing not only upon the outlay more or less of some thousands of pounds, but upon the well-being and recovery to health of thousands upon thousands of the human family in coming years, that we are not surprised to find it awakening week after week the solicitude of all thoughtful minds. The cost involved in the different sites has formed one great point in the discussions which have already taken place; but to us it appears reasonable that the best position for the object in view ought to be chosen even at the additional expense (if it should be so, which is doubtful) of a few thousand pounds. Let that be done, and we feel sure that when all feeling upon the subject has subsided, every one will be satisfied, and be justly proud of an institution well worthy of the great city to which it belongs. We have already referred to the opinions of Professor Syme and Dr. Andrew Wood, both of them authorities whom it would by no means be wise to disregard; to-day we give some quotations from a letter of Dr. James D. Gillespie, Surgeon to the Royal Infirmary. He says:—

"I think it is a great pity that some of the most influential contributors to the Infirmary building fund have not indicated their views regarding the question of site, trusting, I fear, too much to the judgment of the few who have formed a committee with the managers. It appears to me that these gentlemen have allowed themselves to be ruled in the matter by a majority of the Infirmary managers, who, from what has taken place in former years, are not likely to be impartial judges on the merits of the case.

"I cannot understand how there possibly can be two opinions as to the preferable character of Watson's Hospital grounds for the new building. If 'A Contributor' will take the trouble to look at the rival sites as blocked out in the Post-Office Directory map, he cannot fail to see how preferable in every respect the large, unhemmed-in space sloping to the south must be; but if he wants further confirmation, let him stand near the Infirmary dead-house and gaze up at the eight storeys of Drummond street, the only *sunny south* to which the Medical Hospital can look.

"In conclusion, I may add that, as my term of office as ordinary surgeon expires in two years from this date, I have no personal object to gain in my advocacy of a change of site, for ere either plan has been completed, my connection with the Hospital will have ceased; but having now for thirteen years held the responsible position of acting surgeon, and having at a more distant period resided for nearly two years in the building, I can judge of its defects, and I would be sorry indeed to see such a glorious chance thrown away of building a general hospital in such an eminently genial locality as Watson's Hospital, and suited to the requirements of the advanced age in which we live."

EDINBURGH AND GLASGOW PRISON DIETARY.

Mr. Thomson, resident surgeon of the General Prison for Scotland, in the annual report of the managers appointed under the Act of 1860, says that from statements made by the resident surgeon, and other matters falling under our notice, we had reason to believe that, in the Prison of Edinburgh and the Prison of Glasgow, male convicts under sentence of penal servitude did not receive the dietary prescribed by the rules adopted and issued by the Secretary of State for the Home Department.

After discussing the matter with Dr. Christison, who concurred in his conclusions, he states them briefly as follows :—

1. That the scale of dietary substituted in Glasgow Prison for that sanctioned by the Secretary of State appears to be inadequate in its alimentation, and has been attended by several severe cases of disease of a scrofulous nature.
2. That the scale of dietary substituted in the Edinburgh Prison, although in a less degree than that of Glasgow, has been followed by a somewhat reduced physical condition of the male convicts in some cases of disease ; and looking at its defect in the article of meat, in my opinion would prove unsatisfactory for male convicts.
3. That the reasons offered by the County Board of Edinburgh Prison do not, in the opinion of Dr. Christison and myself, justify a departure from the scale of dietary, No. VII. of the Dietary Rules, sanctioned by Sir George Grey on 1st May, 1866, for male convicts.

ST. ANDREWS.

Mr. Froude was installed as Rector of this University on Friday last. The ceremony was performed in the upper hall of the University Library, Principal Tulloch presiding. There was a large attendance. Principal Tulloch referred to the distinguished position Mr. Froude occupied as a man of letters and historian, and alluded especially to his works on the Reformation. He said the University was proud to enrol such a name on its list of honorary graduates. The degree of Doctor of Laws was then conferred on Mr. Froude, and he was invested in his robes of office as Rector amid loud cheers. Dr. Froude then delivered an address to the students, in which he referred to the Reformation in Scotland, the questions of education, University training, &c.

His Grace the Duke of Portland has appointed Dr. Auld, Classical Master in the Madras College, to the Chair of Humanity in the United College of St. Leonard and St. Salvator, St. Andrews.

Notes on Current Topics.

A Royal Academy of Medicine.

Our readers are aware that for a long time a Committee of the Royal Medico-Chirurgical Society has been busy with a scheme for creating an Academy of Medicine by the amalgamation of the societies that divide too much the attention of medical men. It does seem strange, certainly, that up to the present time we have no such institution as an Academy. It is an illustration of the want of union that has always characterised British medicine. A definite proposal has at length been agreed upon. The Committee recommend the Society to change its name, and to group round it, as sections, the Clinical, Pathological, Epidemiological, Obstetrical, and Psychological Societies, by admitting their Fellows and Members as original Fellows of the Academy on their payments being made equal to those of existing Fellows of the Medico-Chirurgical Society. It is possible this plan, with some modifications, may ultimately be accepted, and Mr. Solly's wish become accomplished. The Societies named may easily consent to such an arrangement ; but there are other Societies, and we should like to know whether, as a whole, they would not consent to the terms of the promoters, if the Academy would be prepared to extend to individual Fellows similar inducements. Certainly, when the youngest Society, with no claim at all, is thus treated, Fellows of older associations should, as individuals, be invited to become original Fellows of the new Academy. Nothing can be more desirable than that the new Academy, if instituted, should have the universal support and confidence of the profession, and we therefore hope that the scheme may be so revised as to give it a decidedly wider basis. The scheme as submitted by the Committee, which is too long to be introduced into this article, could easily be amended in the sense we have indicated.

The Pharmacopœia.

A reprint of the British Pharmacopœia is in the press, and will be issued before long. In two years 18,000 of the 20,000 copies printed have been sold, and the demand is still active. We believe that no revision, beyond the correction of typographical errors, will be made in the forthcoming issue, which will thus not be a new edition, but simply a reprint.

Peroxide of Hydrogen.

M. Stohr, Assistant Physician at Würsbourg, has published a series of researches to prove that oxygenated water, or peroxide of hydrogen, applied for a long period to soft chancres reduce the period of healing by one-half. At the same time, this liquid takes from chancrous matter the property of inoculation, and consequently deprives the chancre of all its specific characteristics. Occasionally it is essential, in order to obtain the latter result, to apply a large quantity of concentrated water; for the author has satisfied himself that it requires ten parts of the agent to neutralise one part of chancrous pus in order to deprive it of infecting power.

The same remedy has given marvellous results in cases of diphtheritic ulceration after other remedies have completely failed. The contagious character of diphtheria seem annihilated by the oxygenated water, which, however, is not to be regarded as a caustic, properly so-called, for it does not destroy tissues, but acts rather on the liquids of the parenchyma, the serosity of the blood, and pus.

Locality of Disease.

The influences of locality on disease, and notably on heart affections, dropsy, and cancer, were brought last year under the notice of the Health Section of the Social Congress and of the Medical Society of London, by Mr. Arthur Haviland, in two communications, which, we understand, will shortly be published in abstract. In his investigations on the subject of heart disease the author had fallen upon a fact, the converse of what he had anticipated, that the mortality from that disease was greater in the inland counties than on the sea coast; and not only that, but that the bi-diurnal change of air from the efflux and influx of the tide was a very powerful element in reducing the mortality. In other words, the death-rate was always less in the estuary of a river than in a flat country.

Mr. Haviland's investigations into the geographical distribution of cancer are equally interesting. The result of his comparison of registration statistics is, that he finds the mountainous districts of Wales, and the north and south-east of England, are peculiarly free from excessive mortality of this disease, while the localities of greatest mortality are observed to surround the great rivers after their full formation, and the low-lying valley lands.

The great distinction, however, between the distribution of heart disease and cancer is to be found in the fact that the valleys in which are the *sources* of our rivers are the especial haunts of heart disease and rheumatism; whereas, we have seen that these elevated valleys are everywhere characterised by a low mortality from cancer. Phthisis was shown to have a geographical distribution almost the reverse of cancer. There can be no doubt that, as a rule, cancer is very fatal in towns, but not more so than in the country, and certainly not in proportion to density of population.

Whatever *sequitur* is to be deduced from Mr. Haviland's facts, the investigation is equally interesting and valuable, and by directing attention to peculiar characteristics of locality, will go far towards elucidating the etiology of these diseases.

City of London Hospital for Diseases of the Chest, Victoria Park.

THE twenty-first anniversary festival of this hospital was held on Wednesday, March 17th, at the London Tavern, under the presidency of Lord George Hamilton, M.P.

There was a large gathering of the friends and supporters of the institution, and the noble Chairman made a very happy and productive appeal on behalf of the hospital, resulting in subscriptions and donations to the total amount of £3,800. It appears that the district of Bethnal Green, where the hospital is situate, contributed £500 towards the above-named sum, showing how highly the institution is valued by the working men's clubs, as well as by the great business firms, in the neighbourhood.

The medical report showed that there had been 664 in-patients during the past year, and 14,996 out-patients. At present the Victoria Park Hospital makes up 120 beds, for which there seem to be always a crowd of applicants. The completion of the hospital, by the erection of the other wing, will materially add to its capacity for receiving more in-patients into the wards.

Among those present at the dinner were the Treasurer, Mr. Tucker; the Sheriffs of London and Middlesex; and of the medical staff, Dr. Risdon Bennett, Dr. Birkett, Dr. Andrew, and Dr. Thorowgood. The toast of the "Medical Officers," proposed in a short but expressive speech by John Williams, Esq., V.P., was responded to by Dr. Andrew.

Sir Patrick Dun's Hospital.

THE meeting of medical officers of clinical hospitals in Dublin, to which we alluded in our last, took place on March 16, at the Royal College of Surgeons in Ireland. It was convened by a circular signed by an influential representative of every clinical hospital in Dublin, with the exception of Sir Patrick Dun's, and was largely attended. As our readers will recollect, its object was to take such steps as might be approved to have the restriction annulled which obliges candidates for the degrees and licenses of the University of Dublin to attend at Sir Patrick Dun's, in preference to any other hospital. The chair was occupied by Mr. W. Colles, surgeon to Steevens' Hospital, and secretary of the Royal College of Surgeons. In opening the meeting, the chairman entered on a brief explanation of its objects, and of the history of the restriction which was felt to be an injustice.

Dr. Benson, Professor of Practical Medicine in the Royal College of Surgeons, proposed:—"That the regulation of the University of Dublin which obliges candidates for its degrees and licenses in medicine and surgery to produce certificates of nine months' attendance on Sir Patrick Dun's Hospital, being calculated to restrict the free choice of students in respect of their hospital attendance, ought to be annulled."

This resolution was seconded by Mr. Stapleton, surgeon to Jervis street Hospital, and was unanimously passed.

It was then proposed by Dr. Head, physician to the Adelaide Hospital, and seconded by Dr. Gordon, physician to the Whitworth Hospital:—"That a memorial to the provost and senior fellows of Trinity College be prepared, requesting them to take into their consideration the regulations in respect of the hospital attendance required for the degrees of the University."

Mr. Tufnell, surgeon to the City of Dublin Hospital, proposed, and Mr. Fleming, surgeon to Steevens' Hospital, seconded, the appointment of a sub-committee to prepare the memorial, and the meeting adjourned.

A very strong feeling on the subject to which this meeting devoted itself exists in the mind of the members of the profession in Dublin, and it is believed that the temperate suggestions of the influential persons who have expressed themselves on the subject will receive every favourable consideration from the University authorities.

Scientific Lectures at the Royal Dublin Society.

PROFESSOR GALBRAITH delivered, on Saturday last, a most interesting lecture, the first of a series, having chosen the subject of the metric system of weights and measures. The next lecture, by Dr. Mapother, on the wonders of the circulation, will take place on Saturday next, at four o'clock, when the spectroscopic appearances of blood, the new colour test, and the circulation in the frog's web, by the oxy-hydrogen light, will be shown.

Fees to Medical Witnesses in Ireland.

AT length our Irish readers may indulge the anticipation that the condition of the law which left the profession hitherto at the mercy of attorneys in the matter of fees for expert evidence is likely to be amended before long. The Common Law Procedure Act, which was brought in last year by Mr. Chatterton, then Attorney-General for Ireland, contained a clause empowering the judge to fix remuneration for evidence when he shall think fit. Hitherto no such power had existed, and unless the medical witness had previously pledged the attorney on whose *subpœna* he appeared to some certain payment, he was entirely dependent on his good feelings whether he received anything at all. In point of fact, medical men were often summoned to give evidence, and kept waiting from day to day, and afterwards received nothing but a shilling for their trouble. Mr. Chatterton's Bill was pushed aside last year, with a legion of other useful measures which suffered asphyxiation at the hands of the Irish Church resolutions. It has been re-introduced this year, and will, we trust, make a more conclusive progress through Parliament. If it should pass, it will, of course, effect nothing more than the conferring of arbitrative power on the judges, who have, however, never hesitated about making a fair return for legal services in their courts.

The Cantor Lectures on Food.

WE are informed by the *Philadelphia Medical and Surgical Reporter* that Messrs. Townsend and Adams, a firm of well known American publishers, have in the press a reprint of Dr. Letheby's very interesting and valuable Cantor Lectures on Food, delivered before the Society of Arts, and published originally in the MEDICAL PRESS AND CIRCULAR. These lectures were afterwards copied into the *Chemical News*, and have now found their way across the Atlantic. Professor Seely has written the prefatory observations, and such annotations as he considers that the lectures may require.

The next Army Examination.

WE learn, on good official authority, that the probability of admission to the Army Medical Service is very remote. August 1870 is named as the earliest period at which it is probable that a competitive examination may be held, and as it is improbable that many of the present expectant candidates would be disposed to postpone their entrance into the practice of their profession for a year and a half, we anticipate that there will be many seekers for vacant medical offices.

The Contagion of Consumption.

M. CHAUVEAU, Professor in the Lyons Veterniary School, continues preseveringly his researches on the Contagiosity of Tuberculosis. He has of late selected the intestinal surface as the field for his investigations, and through it by introducing tuberculous matter into the circulatory current he has produced at will general tubercle. The *Union Médicale* reports that he lately purchased four handsome heifers, and he tuberculised three of them by causing them to swallow 30 grammes, each of tuberculous matter taken from the body of an old phthisical cow. The rapidity of the result was extraordinary. At the end of twenty days the first heifer had lost flesh to a surprising extent, its pulse was quick and full, and it coughed incessantly. At the end of fifty-two days it was killed, and it presented perfectly marked tuberculous lesions situated especially about the mesentery and intestine. The mesenteric grands presented infiltration in so high a degree that many were of the size of the first. Their total mass weighed 1,650 grammes. All the ganglia of the bronchi and mediastinum were enlarged, and the lung was full of crude tubercle. The other two heifers presented not less perfectly marked alterations, while the fourth, to whom none of the tuberculous matter had been administered, remained intact and increased in flesh.

It is proved, therefore, that animals of the bovine species contract tuberculosis by digestive ingestion, just as they take carbuncle and cowpock, as sheep take the rot, as the horse takes glanders, and as man takes small-pox. The human digestive tube constitutes an easy channel for tuberculous contagion. If bovine phthisis be identical with tuberculosis in the human species, there is, in the use of the flesh of tuberculous animals, a danger to which the poor are more especially exposed.

Poisoning by Arnica.

A CASE occurring in a woman of 33 years of age, is reported in *Schmidt's Iahrbücher*. She had drunk two glasses of infusion made from a large handful of the leaves. The symptoms of poisoning lasted seven days, and the patient was not quite well till the 12th. The prominent symptoms were violent vomiting, intense headache, choleriform diarrhœa, with very severe gastro-intestinal colic, followed by collapse, cold extremities, and remarkable depression of the pulse. The treatment consisted principally of the use of extract of thebaine and of morphine.

New Fungus in Cattle Fever.

DR. PURDON, of Belfast, favours us with an extract from a letter of Professor James Law, of Cornell University, in America, in which he announces the discovery of a new fungus found in the blood and bile of Texan cattle, after death. They appear first as groups of clear refrangent spores, unstained by bile, which presents a marked contrast to the common yellowish germ elements of the bile. They, after a few days' cultivation, enlarge, and show a tendency to elongate, if not to form a mycelium. The fungus is suppposed to resemble very closely the *cryptococus guttatus* of Hallur, and may prove to be identical with it. The blood globules of the animals have a tendency to rapid disintegration, and the addition of the bile to healthy blood induces a rapid breaking up of the blood particles, though of course it is impossible, without further investigation, to say whether or not this is caused by the cryptogam.

The Midwifery Diploma of the London College of Surgeons.

A MOST important reform has been proposed at the London College of Surgeons—viz., that midwifery should be included in the examination for the membership. This will lead to the suppression of the diploma L.M., which is certainly a step in the right direction. The profession is indebted for this proposition to Mr. Curling, whose position in the council of the college, in the profession, and at the London hospital must secure for him the attention that might have been denied to reformers of less renown. Nothing can give the younger members of the profession more hope and more pleasure than to see gentlemen who have achieved the highest honours, and hold them so worthily and withal so modestly, thus concern themselves with the subjects that all medical reformers have so much at heart. We hail Mr. Curling as one of the natural leaders of medical reformers.

Mr. Adams.

THE retirement of Mr. John Adams from the post of Senior Surgeon to the London Hospital, and his election to the Consulting Surgeoncy, demand a notice from us.

We noticed a few months ago, that this distinguished surgeon and teacher—the oldest professor of anatomy in the metropolis, if not in the kingdom—had resigned his chair (of anatomy) in the college attached to the hospital. After very many years of active and faithful service, we now see him accepting the *otium cum dignitate* of the consultancy. We recently printed the first lecture of his successor in the chair—Mr. Walter Rivington—whose tribute to his predecessor fully justified all we had said of him. We would also refer to some of Mr. Adams's clinical lectures published in our pages last year. They exemplify alike his zeal as a surgeon and a teacher. We desire once more to express our thanks for the many lessons for which we are indebted to Mr. Adams, and our sincere wishes that he may long live to give his valuable advice to those who will continue to call him into consultation.

Miss Nightingale on Pauperism.

The "Note on Pauperism" which has been so freely advertised as the attraction of *Frasers' Magazine* like all from the pen of that estimable lady will be read with interest. Miss Nightingale would send all sick paupers to hospitals—which we really *profess* to do. Then the children she would distribute throughout the country as boarders, with people who would bring them up to labour. This seems to us the weak part of the plan, for it would barely be possible to find honest, well-to-do, sensible, industrious labourers in numbers sufficient—nor could they be trusted to do their part fairly by the children, and any plan of inspection would be both difficult and expensive. School is far better for both boys and girls than the chance of being drudges to ignorant or drunken or cruel task masters.

As to the others—adult paupers, having taught them how to work, and where there is a scope for labour, Miss Nightingale would organize them into colonies, and settle them on wild lands—say in Australia. So far good, but how to get them there? Are we to compel them to emigrate? If so, would not some call it transportation?—An ugly wind that might destroy the whole scheme. Many industrious men would only be too glad of the chance to emigrate, and we know of no better use to put charity to, than to encourage this palliative of our social cancer. But after all, the mass of paupers belong to a different order, and we fear nothing but hunger, or the iron hand of the law, compulsorily driving them from their haunts will change their habits, and transform them into workers instead of drones.

The Weather.

March storms are not over, if we are to credit the predictions of Karl Balla. That meteorologist prophesied on the 24th February the storms that have swept over England and France already this month. In a letter dated from the neighbourhood of Pesth, he foretold that the storms would begin on the 11th, and be felt in various parts on the 12th, 13th, 14th, and 15th days. Then they would subside for a time and break out afresh. Finally, he says, a new series, more violent, will sweep the English coast and a large part of France. The Bay of Biscay, the Mediterranean, and the Grecian Archipelago, will all feel them. The Channel, however, is to be the centre, and this series is to rage from the 20th to the 27th, at intervals, coming to the greatest height on the 27th, after which it will subside. We have not had the opportunity of remarking the accuracy of the former part of this prophesy, but as to the latter part, stormy weather most certainly set in on the 20th. We shall wait for the 27th to see if his prophesy is true to the letter.

Hodson v. Harrison.

On Friday last, the Court at Cheltenham was occupied in hearing the appeal case granted to Mr. Sims Reeves in the trial Hodson *v.* Harrison. The principal witness, Dr. H. W. Rumsey, who was unable to appear when the case first came before the magistrates, now gave evidence on behalf of the defendant. He stated that when called in to see Mr. Reeves, he found his throat much relaxed and congested, with a want of tone in the action of the heart, and suffering from general debility of the system. He prescribed remedies for him, which he hoped might give relief, but from the first he had grave doubts as to the ability of the defendant to fulfil his engagement that evening. This proved unfortunately to be the case, although the treatment adopted had so beneficial an effect that he was enabled to sing the following night at Worcester. After the evidence of Dr. Rumsey, the Judge ordered the remission of the fine inflicted at the former trial, adding, that had he been in possession of the valuable evidence now adduced, he should not have convicted the defendant.

The governors of the London Hospital held a meeting on the 16th inst., at which they appointed Mr. Maunder to the office of surgeon to the hospital.

Dr. T. Fox has obtained the appointment to the Skin Department at University College, vacant by the decease of Dr. Hillier. This will create a vacancy in the same department at Charing-cross Hospital.

The Birmingham branch of the Association for the extension of the Contagious Diseases' Act held a meeting lately. The general feeling was in favour of carrying out the provisions of the Act.

Mr. H. Pitman was charged at the County Police Court, Strangeways, with having contravened the Vaccination Act. He had a conscientious objection he said to compulsory vaccination. He paid the fine of 20s. and costs.

By the will of J. G. Frith, Esq., J.P., the "Dreadnought" Hospital Ship receives a legacy of £500; the Middlesex Hospital, £500; St. Mary's Hospital, £500; St. Mark's Hospital, £150; Royal Hospital for Incurables, £200; Hospital for Sick Children, £200; London Fever Hospital £200.

The murderess, Montauban, about whom certain newspapers in London have been so violently screeching during the past few weeks, has been found guilty, with extenuating circumstances, of drowning nine infants in boiling water, of abortion, and other crimes, and sentenced to the galleys for life. In the name of Justice, we should like to be informed what were the extenuating circumstances upon which a French jury based its recommendation for the clemency of the tribunal towards such a wretch.

THE Leeds magistrates have investigated the charge brought against Richard Atkinson, a person of independent means, of having caused the death of a widow by applying a plaster of arsenic mixed up with acorns, buttercups, and other simples. An inquest had been held, and the jury returned an open verdict. After carefully considering the case, the magistrates decided to dismiss the charge.

BY latest telegrams we learn that His Imperial Majesty, the Emperor of the French, has so far recovered from his serious illness—a cold which he caught while witnessing some gas experiments, and which set Paris in a fever of excitement on Saturday last—that he is able to resume his ordinary avocations. We are therefore happy to record the subsidence of the latest "storm in a tea-pot."

MR. ERASMUS WILSON has munificently presented to the London College of Surgeons the sum of £5,000 to endow a Professorship of Dermatology—the branch of our Art to which he has devoted his life and which he has done more than anyone living to advance. The professorship is not to be confined to Fellows of the College thus benefited, but with true liberality is to be conferred on the best man whatever his legal qualifications.

A SOCIETY is in process of organization at Shorncliffe, through the initiation of Dr. Alfred Clarke, and other medical men resident in the district, which will be known as the Army Medico-Chirurgical Society. Deputy Inspector-General Mure has accepted the presidency, and the association will shortly inaugurate its first meeting, under very favourable auspices, and promises of co-operation from influential quarters.

AT a meeting of the Governors of Worcester Infirmary relative to the death of Thomas Price through the negligence of the dispenser, it was agreed to omit the clause in the report of the special committee recommending the prosecution of Harding. The feeling was that there was great want of discipline in the general management of the institution, and that a special committee should be appointed to inquire into the state of things.

IT may be seen, on reference to our advertizing columns, that Mr. Squire has just cleared from the press a second edition of *The Hospital Pharmacopœias of London.* The author has been indefatigable in his efforts to obtain all the necessary matter to make this volume as useful and as popular as his other work, entitled *Squire's Companion to the British Pharmacopœia,* of which we are shortly promised the seventh edition. The Profession is greatly indebted to Mr. Squire for the care and labour he has bestowed upon the works before us, and of which we have so often spoken in praise.

WE learn with satisfaction that the entire body of Assistant-Surgeons, who had passed the promotion examination at the end of their service at Netley Hospital, have been gazetted to the service.

They are thus at least relieved from the apprehension of being dismissed from the service altogether as they might be, under the operation of the reduction craze, if they had remained simply in the condition of past candidates. We believe that it is not known when they may probably be called into service, but as they are now on full pay that interval of idleness will probably be a short one.

A VERY interesting application of chemistry to the arts was exhibited recently at the Dublin Chemical Club, and subsequently at the Conversazione of the President of the College of Physicians. It has been found that one of the products of fermentation in ale and porter can be effectually replaced by the addition of grape sugar to the liquor, and for this purpose grape sugar is now being manufactured very largely from starch for the use of brewers and extensively imported. The objects achieved by the use of the grape sugar are justly a very considerable saving of the malt, and, as may be anticipated, a considerable reduction in price of malt liquors; and secondly, an increased capacity for keeping in the liquor made with grape sugar, which will make it peculiarly suited to foreign consumption and the export trade, and will obviate the very serious waste which now accrues from the spoiling of the liquor.

Correspondence.

SUGGESTIONS IN MEDICINE.—No. II.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—My next suggestion, or rather series of suggestions, is with respect to—

PHTHISIS PULMONALIS, OR CONSUMPTION.

This wide-spread malady, the endemic plague of the English people, and reproach of physicians, claims all attention. It is true every respect has been paid to it of late years, especially in this country. In fact, there has been talent of such high order employed in the investigation of its nature, and men of such consummate tact and ability engaged in its treatment, that it may appear presumptuous in any ordinary mortal even to approach the subject. But what member of the profession, however humble, has not had cases under his care? Who has not observed its ravages among the noblest and most amiable of his species, and how often it has filled the tomb with youth and genius? He must be a poor philanthropist indeed, who could mark all this unmoved, and not wish that a happy thought might strike him—that, like certain idiots, he might be temporarily inspired—so that through him this saddening evil might be lessened or destroyed. In this way I have often ruminated, perhaps to little purpose; but I now communicate the result of my reflections, and will hope that, as my notions are original, some of them at least may be practically useful. In general terms I will state the high problem to be solved.

By pathologists, tuberculosis is regarded as a constitutional, or blood disease; and such undoubtedly it is. It pervades the whole system. Believed to depend on some obscure arrest or perversion of assimilation, matter very slightly if at all organised is deposited in various tissues of the body, giving rise to more or less disturbance of the functions. When seated in the lungs, it is called tubercle, and is the *fons et origo* of the disease under consideration. Physicians seem now to agree in regarding this deposit as dependent on that bad habit of the system, by which the fatty matter contained in food is not assimilated in sufficient quantity to meet the waste occasioned by respiration. Hence, the now almost universal practice of trying to rectify this faulty nutrition by the administration of oily matters in some form easy of digestion. Yet why the non-assimilation of fat should cause this tuberculous deposit is by no means made clear. It is stated merely as the fact.

Pulmonary tubercle is usually at first of the consistence of cheese, and is deposited in the air-cells and minute bronchi, as well as in the inter-cellular structure. Of this I am assured by repeated microscopical observation. The upper lobes are most frequently affected at the beginning; but tubercle may, and often does, prevail throughout the entire viscus. In some rare cases it is confined to one side of the thorax—to affect one lung solely. In this stage it must derange the health by obstruction or occlusion of the vessels and prevention of aëration—hence difficulty of breathing and loss of strength. Impeding the circulation there is more or less hæmoptysis, probably depending more on exudation than rupture of the vessels. After a time, if the disease progresses, softening of the tubercles takes place; the cheesy is converted into a creamy matter, erosion and ulceration of the cellular structure, attended with great constitutional irritation, ensue. The lung is then studded with abscesses, technically called "vomicæ," of various sizes, until at length the viscera are completely spoiled and unfitted for their office. Thus the patient sinks from the effects of constitutional irritation, exhaustive discharges, and insufficient aëration of the blood. Of course these various changes are attended with a variety of other symptoms unnecessary to describe. But one of the most remarkable and interesting phenomena is the little change apparent to the ordinary observer previous to dissolution. Friends are deceived into hope when all is hopeless. A bloom of apparent health, and certainly of beauty, often pervades the hectic cheek, that, like the varied coloured tints on the crumbling ruin, charm the eye and wrap the departing spirit in a cloud of glory. Another characteristic may be generally observed. Whether due to the exhausting nature of the complaint, or the absence of exciting material in the blood, the consumptive patient generally displays such patience and amiability that he wins completely the hearts of those around. On these accounts the victim of phthisis is regarded with especial interest, and, while deploring his untimely fate, the wish returns with redoubled energy that a check could be given to the fell destroyer.

The symptomatology and diagnosis of this complaint are as perfect almost as could be desired. Auscultation and percussion are wonderful methods of research; albeit few of the present day could do as much with the stethoscope, or foretell the hour of death by its means, so well as did the great Laennec. Yet it is a clumsy instrument after all. Numerous little changes have been made in its form, and some in the material. Still a return is made almost to the original model—a rigid wooden tube enlarged at the extremities. That physicians are able to effect so much with such primitive means, only shows the tact that arises from the education of the ear. In use it looks awkward and barbaric in the extreme. The ends must be applied flatly both to the ear and to the body of the patient, or the effect is *nil*. Hence, when the sufferer is in bed, the doctor has to place himself in the most singular postures, with a hand at each extremity of the instrument, and his head turned away from the patient. Or he kneels and twists his body by the bedside in a way painful to behold.

The flexible metallic tube of some operators appears a degree better, but still has the disadvantage of needing the constant employment of both hands while in use, and a bag to hold it in afterwards. Now what I would respectfully suggest is this. Let an instrument be constructed by which both ears, if they are sound, may be employed, and one hand at least be at liberty. Moreover, let the auscultator be enabled to look straight before him to see what he is about. Now, I believe all these desiderata might be effected in this wise. A band of stiff leather made to fit the head tightly—either open at the top or in the form of a smoking cap—would have affixed to it a couple of flexible auscultatory tubes with bell-shaped extremities. It will be obvious that this could be readily adjusted to the ears, and that the hand directed by the eye could commodiously adapt an orifice to any part of the patient's chest. Or, when it became necessary to examine both sides for the purpose of comparison, a tube could be applied to each at the same moment and the resultant sounds investigated. There is no necessity to have this head-gear unsightly or inconvenient for portage. Lightness and elegance could be consulted, and the whole stowed away within an ordinary hat.

If a small sounding board and hammer could be connected with this acoustic tube, great advantage would result apparently. At present, percussion with the fingers, by which the sound travels to the ear through a long space of atmosphere, seems extremely mechanical and unscientific. It is quite true that great results are effected by such means, and those who are educated to its use seem quite satisfied. Still the objection remains. Is there not a probability that greater results would be obtained if the appliances were more perfect?

Now we come to the most important department of our theme—namely, the treatment of consumption. And here I am prepared to offer several suggestions, which may or may not be of value, although I fondly cherish the hope that they will sooner or later prove so. Time alone can show. Many a proposition made in all faith and sincerity has been scouted, laughed at, and ridiculed, that has eventually been adopted with advantage. The history of discovery shows this. So I am prepared to receive the blows of martyrdom, and cry, "Strike, but Hear."

In the first place, the question arises—Is consumption of the lungs curable? The quack answers, "Yes," boldly, and deludes the patient and his friends. The conscientious physician devoted to this department answers, "Yes," also, although with a little more caution and reserve. But does he carry out this assertion? Assuredly not, I reply. Yet I have no wish to depreciate the value of the modern treatment, climateric, hygienic, dietetic, and so forth, employed by the regular practitioner; or the great service rendered by cod-liver oil and its cogeners. Doubtless they are often extremely beneficial; though merely to delay the fatal hour—to arrest for a time the hand of the great destroyer. But some would here exclaim: "What do you want more? We must all succumb to death sooner or later." Certainly we must. What I wish to state is, that the phthisical patient generally dies from phthisis in despite of all treatment. The hour comes when the vaunted specifics lose their power or cannot be employed, and the sufferer sinks into a premature grave. Exceptional cases prove this rule.

If any real impression had been made on this scourge of Englishmen, would not the statistics show it? Would not the number of deaths put down to this cause be lowered? Assuredly. All educated practitioners are acquainted with the most approved modern remedies, and employ them continually. Yet the bills of mortality still show a fearful list of deaths from consumption. The percentage, I imagine, is but slightly altered. In the face of this fact I think it is absurd to say that phthisis is cured in these days, that the remedial means in use are all-sufficient. They are not so.

Yet I should be sorry to be misunderstood on this point. I consider the fish oils, &c., extremely valuable; but merely as adjuvants. The real curative means are yet to be made known and applied. Modern research would seem to point in the direction of hygiene.

If I, as an individual, were asked whether I consider this complaint past remedy—that it never will be curable—I should answer, "Certainly not." Nature herself proves the contrary. Cicatrices of old vomicæ, scars of abscesses of the lung that had healed spontaneously—that is, by the *vis medicatrix naturæ* unaided—are, as is well known, repeatedly found in the bodies of those who have died from other causes. These show incontestibly that a cure may be effected, although the *modus operandi* is not understood. It is a problem difficult of solution, but that it will be solved some day we have every right to expect.

Under these circumstances the following suggestions are offered. It is useless proceeding in the same beaten track, running in the same groove, for ever. Radical changes when needed are made in every department, and often with manifest advantage. Why should medicine be exempted? It is true, life—human life—is the stake to be played for, and caution should be employed. But if this same life be already almost doomed, surely a bold cast may be hazarded for its redemption.

Your obedient servant,

Bath, Feb. 1869. TOOGOOD DOWNING, M.D.

(To be continued.)

◆

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been directed to an interesting article on a Congenital Malformation of the Œsophagus, described by Mr. Annandale in the last number of the MEDICAL PRESS, and to the fact that a preparation of a similar case is in the Museum of this College. The preparation alluded to has been in the Museum for the last forty years, and is still in a good state of preservation, and exhibits the almost exact relations of parts so well described by Mr. Annandale. A full account of it will be found in the fifth volume of the "Dublin Hospital Reports," a work replete with the best information on medical subjects. Dr. Houston there figures and describes this case as having occurred while he was Curator of the Museum of the College.

Yours faithfully,

JOHN BARKER, M.D., Curator.

◆

PRACTICE *v.* DIPLOMAS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At present there appears to be a very slack enforcement of the law in regard to those assuming medical degrees which they do not possess, as I can name several who, relying on the unwillingness of medical men to prosecute, boldly affix M.D. or Surgeon to their names.

Would you believe that a gentleman could be so far lost to all promptings of honour and integrity, as to solicit a testimonial from an eminent M.D., who took him at his word, and stated that he was a Licentiate of a Royal College, who deny, on inquiry, that any such person ever obtained their diploma?

I would feel obliged to any gentleman who would give me information on the following case, as to how the hero could be brought to a sense of duty and a knowledge of his proper position:—

A *Friendly Society* in Dublin was lately competed for, and a Mr. D— was elected. Now this gentleman is registered as a Licentiate of the Apothecaries' Hall, Dublin (though proposing himself as a surgeon). Again, he calls himself Doctor on his time-cards, and emblazons his window screens with Doctor D—, Surgeon, in four-inch gold letters; yet modestly styles himself as Apothecary and Accoucheur on his bottle labels. He does not hold any surgical diploma. Is he not liable to prosecution on two charges? For holding the appointment of surgeon to a friendly society, and taking the title of Surgeon unlawfully?

Now-a-days, that quackery *outside* the profession shares deservedly a large portion of our resentment, and defies, under existing legislation, a severe punishment or just suppression, we ought to be doubly cautious of quacks within our own sphere, who, either by advertisement or assumption of degrees, seek to mislead the public.

Hoping you will give this early insertion,

I am, &c.,

March 18, 1869. JAMES DUNNE, M.R.C.S.

[Our correspondent has to thank the Medical Act for putting such offences as these beyond the reach of legal suppression. Without doubt it is a false pretence for any person to call himself Surgeon or Doctor who is neither one or the other, but, as far as the law declares, an L.A.H. is as competent to accept and enjoy any professional appointment as any Doctor, Fellow, Physician, or Licentiate.]

◆

Literature.

A DICTIONARY OF MATERIA MEDICA AND THERAPEUTICS.

By Adolphe Wahltuch, M.D., L.R.C.P. Lond.

TRULY this is the age of book-making. Every man must needs be an author; and medical literature teems with its countless aspirants to fame. We fear the press are in some degree to blame for this, as there seems to be less of that impartial criticism applied to medical literature than to that which aspires to notice in the various Quarterlies and Reviews where the chaff is winnowed from the grain. However, in the present instance, we shall not fail to do our duty as impartial critics.

Our author wishes to guard against being thought to cater for the notice of the unlearned public, and therefore he tells us that his work is intended "as a book of reference for the busy practitioner, whose memory may now and then require assistance, or who may wish to be guided in difficult cases by the formulas of others."

Now we think that if the "busy practitioner's" memory fail respecting doses and the most ordinary therapeutic and physiological actions of drugs, he would at least prefer a more portable volume than that which Dr. Wahltuch has presented him with, which is larger and heavier than the British Pharmacopœia.

We cannot see anything to recommend the tabular form in a work on materia medica where the object is minute detail for reference, as with a good index there can be no delay in acquiring this information from any good book on the subject. On the contrary, the tabular form excludes all that minute detail respecting the conditions which modify the dose and action of drugs, without which it is impossible for any scientific physician to write a rational prescription.

There is an old saying that "what is one man's food is another's poison," and while Dr. Wahltuch recognizes the truth of this as regards the empiric use of formulæ, he does not hesitate to encourage the malpractice by grouping together the formulæ of practitioners in countries where the officinal preparations prescribed are totally unlike in strength, colour, composition, &c. In fact, some of these formulæ become absurd when regarded as compounded according to the British Pharmacopœia. How different, for example, would the formulæ of Paris, Trousseau, Still, Oesterlen, and Kummerfeld be, when compounded according to our codex, from that which were intended to be used; nor are the formula of our own well known writers, Copland, Christison, and Neligan, any guide to the physician of 1869; this will best appear from the perusal of the following prescription (No. 474, p. 180) said to be Neligan's:—

℞ Linimenti Belladonnæ, ℥viij;
Tincturæ Belladonnæ, ʒij;
Fiat linimentum sæpe utendum.

Now, what rational man would think of adding two drachms of a weak preparation like the tincture to 8 oz. of such a strong saturated formula as the liniment of our present codex? We think that to order 8oz. of the Pharmacopœial liniment is scarcely justifiable on any grounds.

Again, it must be confessed, that either prescriptions should be written altogether in English, or, that, at least, the Latin used should be grammatical; but whether it be due to the carelessness of the several prescribers, or to want of time in the editing of the work, there can be no doubt that the blunders are too numerous to be made light of. The genitive case is often omitted when it should occur and inserted when the accusative should appear. Such sentences as "ut *fiat* pilulæ viij," "Capiat *cyathus vinarius*," "cum vitelli ovorum vi," and a host of others equally shocking, are surely more than can be set down as printer's mistakes. Such genitives as "querci" and "spiriti" make their appearance now for the first time in the Latin language.

We fear that in attempting to curtail the characters of the drugs, Dr. Wahltuch has often omitted those which are most specific, and we feel sure that the directions given for making most of the preparations are so wanting in accuracy of detail that they would be useless to any one who did not possess a copy of the Pharmacopœia. There is, however, a very fair list of the various synonyms of the drugs, and this will prove useful to those who may have to consult the works of French, German, Russian, or Italian authors.

We cannot see any special advantage in the classification adopted by Dr Wahltuch: it perpetuates such worn-out terms as "alterative," and it groups together deodorisers and disinfectants under the antiseptics! We cannot see why nitric acid is not quite as much an antalkaline as sulphuric acid, and we are surprised to find mustard omitted from the emetics while such doubtful emetics as scoparium and buckthorn are included.

There are some very useful tables of weights and measures in the end of the work, and, what we are always glad to see, a very fair index. The paper and binding are excellent and do credit to Messrs. Churchill and Sons.

Gleanings in Medicine, Surgery, and the Allied Sciences.

ERGOT IN THE TREATMENT OF PURPURA.

DR. BAUER, of Neutershausen (*Deutsche Klinik*), reports great success in the treatment of purpura hæmorrhagica with secale cornutum. He gives 8 to 10 grains three times, or oftener, daily, until hæmorrhagic manifestations cease. When anæmia remains he treats it with chalybeates.

ATROPIA AS AN ANTIDOTE TO OPIUM POISONING.

DR. M. S. BUTTLES relates (*Med. Record*) the following case occurring in his practice, which shows the value of belladonna in cases of poisioning by opium:—"Mrs. W. aged 38, had been troubled with retroversion, perimetritis, and severe endometritis, and has had several severe attacks of pericarditis, which have left extensive adhesions. Had severe neuralgic pains all along the left side, for which I had been in the habit of giving her subcutaneous injection of gr. ss morphiæ sulphatis. On January 20th last, I gave her one of these hypodermic injections, which gave but slight relief; the next morning I repeated it injecting exactly ♏ xv. Magendie's solution (equal to gr. ss morphiæ), and remained in the room fifteen or twenty minutes, when she seemed a little easier, and I retired to my office down stairs; but was very soon summoned by the nurse, who stated that Mrs. W. was dying. I found her lips purple, the respiration seven per minute, no pulse at the wrist, but one sound at the heart; pupils contracted to a fine point, frothing at the mouth, and the extremities cold. I commenced artificial respiration (for while I was cogitating on my handiwork, she entirely stopped breathing), which by myself and assistants was kept up for about half an hour, when I attempted to give her some strong coffee, but she could not be made to swallow. I had sent for several neighbouring physicians, who were all out; but just at this moment my friend, Prof. Chas. A. Budd, providentially called on me, and was immediately shown to the room. He declared that she was dead, and 'laughed in his sleeve' at the idea of keeping up artificial respiration. By this time I began to think of sending for an undertaker (for she had come to me from a neighbouring city for treatment), but as a 'drowning man clings to a straw,' so I was eager to give her every possible chance, and asked Dr. Budd to suggest something, at the same time mentioning belladonna, when he said that atropia might be given hypodermically, if I wanted to do something, but as she was dead it would not bring her round. We resolved, however, to try it. By this time artificial respiration had been kept up for an hour and a half. One-sixtieth of a grain of the sulphate of atropia was injected, and in fifteen minutes she showed signs of life, the pupils began very slightly to dilate, and in ten minutes more she began to breathe, and the respirations rose to twelve per minute; in half an hour we repeated the dose, making in all one-thirtieth of a grain of atropia; and in about fifty minutes from the time of giving her the first injection, she returned to consciousness, and is living, now, with a blank in her life of two and a half hours. To Prof. Budd is due the credit of suggesting the remedy."

LACTATE OF ZINC IN EPILEPSY.

Dr. Hart has tried this remedy in combination with belladonna on 240 patients in the Western Lunatic Asylum in Kentucky, all of whom had been affected with epilepsy from three to six years. An improvement took place in all, and in no case did he use it without effectually controlling the paroxysm in from twenty-four to forty-eight hours. His formula was: ℞. —Zinci lactatis gr. xxx; ext belladonna gr. viii; M. ft. pil. x. S.—One before each meal.—*Humboldt Med. Archives.*

OPIUM AND STRAMONIUM.

Dr. J. F. Treuman was called to see a mother and two daughters. They had had paroxysms of ague, and had taken, as they supposed, fennel-seed, but it proved to have been stramonium-seed instead. When first seen the mother and one daughter were raving like maniacs, while the other was rapidly sinking into coma. Tr. opii was at once given, and morphia injected subcutaneously. The youngest girl recovered rapidly, but the others only after having taken several large doses of morphia. The recovery in each case was complete.—*Chicago Med. Journ.*

NEW USE OF IODIDE OF POTASSSIUM.

Dr. A. de Beaufort (*Bulletin de Therapeutique*), reflecting that iodide of potassium is freely eliminated in the tears and uterine mucus, tried it in free doses in cases of chronic inflammation of the lachrymal tube and also in chronic metritis. His success was most decided. He says: "In cases of internal metritis, with abundant leucorrhœa, and all that train of circumstances which render so many women miserable, I have often seen, when all other means have failed, prompt and decided amelioration, and, in some cases, a positive cure, result from the free use of iodide of potassium."—*Philadelphia Medical and Surgical Reporter.*

CASE OF POISONING FROM ATROPIA.

Horing in the *Wurtemb. Med. Corr. Blt.*, 1868, relates the case of a child three and a half years old, that swallowed a solution of one gr. atropia in three drachms of water. Vomiting occurred, and very promptly symptoms of poisoning. A subcutaneous injection of one-eighth of a grain of morphia was promptly practised. Very soon a decided improvement in the condition of the child took place. The pulse fell at once from 160 to 120; the respirations from between 30-32 to 28. By the end of 45 minutes consciousness and speech had returned. In a few hours the child was fully restored, with the exception of some dilatation of the pupils, which continued a few days longer.—*Centralblatt f. d. Medicinisch. Wissenschaften.*
